

Version 6.6.1

The LEDA User Manual

Algorithmic Solutions

Contents

1	Preface	3
2	Basics	5
2.1	Getting Started	5
2.2	The LEDA Manual Page (the type specification)	6
2.3	User Defined Parameter Types	8
2.3.1	Linear Orders	9
2.3.2	Hashed Types	12
2.4	Arguments	13
2.5	Items	13
2.6	Iteration	15
3	Modules	17
4	Simple Data Types and Basic Support Operations	19
4.1	Strings (string)	19
4.2	File Input Streams (file_istream)	23
4.3	File Output Streams (file_ostream)	23
4.4	String Input Streams (string_istream)	23
4.5	String Output Streams (string_ostream)	23
4.6	Random Sources (random_source)	25
4.7	Random Variates (random_variate)	27
4.8	Dynamic Random Variates (dynamic_random_variate)	27
4.9	Memory Management	29
4.10	Memory Allocator (leda_allocator)	30
4.11	Error Handling (error)	32
4.12	Files and Directories (file)	34
4.13	Sockets (leda_socket)	36
4.14	Socket Streambuffer (socket_streambuf)	39
4.15	Some Useful Functions (misc)	42
4.16	Timer (timer)	44
4.17	Counter (counter)	47
4.18	Two Tuples (two_tuple)	49
4.19	Three Tuples (three_tuple)	50
4.20	Four Tuples (four_tuple)	51
4.21	A date interface (date)	54

5	Alignment Data Types	61
5.1	Alphabet (<code>alphabet</code>)	61
5.2	String Matching Algorithms (<code>string_matching</code>)	63
5.3	Score Matrix (<code>score_matrix</code>)	66
5.4	String Distance Function (<code>distance</code>)	68
5.5	Alignment Functions (<code>alignment</code>)	70
6	Number Types and Linear Algebra	73
6.1	Integers of Arbitrary Length (<code>integer</code>)	73
6.2	Rational Numbers (<code>rational</code>)	76
6.3	The data type <code>bigfloat</code> (<code>bigfloat</code>)	78
6.4	The data type <code>real</code> (<code>real</code>)	83
6.5	Interval Arithmetic in LEDA (<code>interval</code>)	90
6.6	Modular Arithmetic in LEDA (<code>residual</code>)	93
6.7	The mod kernel of type <code>residual</code> (<code>residual</code>)	94
6.8	The smod kernel of type <code>residual</code> (<code>residual</code>)	95
6.9	A Floating Point Filter (<code>floatf</code>)	98
6.10	Double-Valued Vectors (<code>vector</code>)	100
6.11	Double-Valued Matrices (<code>matrix</code>)	103
6.12	Vectors with Integer Entries (<code>integer_vector</code>)	106
6.13	Matrices with Integer Entries (<code>integer_matrix</code>)	108
6.14	Rational Vectors (<code>rat_vector</code>)	113
6.15	Real-Valued Vectors (<code>real_vector</code>)	118
6.16	Real-Valued Matrices (<code>real_matrix</code>)	121
6.17	Numerical Analysis Functions (<code>numerical_analysis</code>)	123
6.17.1	Minima and Maxima	123
6.17.2	Integration	124
6.17.3	Useful Numerical Functions	124
6.17.4	Root Finding	124
7	Basic Data Types	125
7.1	One Dimensional Arrays (<code>array</code>)	125
7.2	Two Dimensional Arrays (<code>array2</code>)	129
7.3	Stacks (<code>stack</code>)	130
7.4	Queues (<code>queue</code>)	131
7.5	Bounded Stacks (<code>b_stack</code>)	132
7.6	Bounded Queues (<code>b_queue</code>)	133
7.7	Linear Lists (<code>list</code>)	135
7.8	Singly Linked Lists (<code>slist</code>)	143
7.9	Sets (<code>set</code>)	145
7.10	Integer Sets (<code>int_set</code>)	148
7.11	Dynamic Integer Sets (<code>d_int_set</code>)	150
7.12	Partitions (<code>partition</code>)	153
7.13	Parameterized Partitions (<code>Partition</code>)	155

8	Dictionary Types	157
8.1	Dictionaries (dictionary)	157
8.2	Dictionary Arrays (d_array)	160
8.3	Hashing Arrays (h_array)	163
8.4	Maps (map)	165
8.5	Two-Dimensional Maps (map2)	167
8.6	Sorted Sequences (sortseq)	169
9	Priority Queues	177
9.1	Priority Queues (p_queue)	177
9.2	Bounded Priority Queues (b_priority_queue)	180
10	Lossless Compression	183
10.1	Adaptive Arithmetic Coder (A0Coder)	186
10.2	Static Arithmetic Coder (A0sCoder)	189
10.3	Prediction by Partial Matching (PPMIICoder)	191
10.4	Deflation/Inflation Coder (DeflateCoder)	194
10.5	Dictionary Based Coder (DictCoder)	197
10.6	Static Huffman Coder (HuffmanCoder)	199
10.7	Adaptive Huffman Coder (AdaptiveHuffmanCoder)	201
10.8	Run-Length Coder (RLECoder)	203
10.9	Burrows-Wheeler Transform (BWTCoder)	205
10.10	Move-To-Front Coder (MTFCoder)	208
10.11	Move-To-Front Coder II (MTF2Coder)	210
10.12	RLE for Runs of Zero (RLE0Coder)	212
10.13	Checksummers (checksummer_base)	214
10.14	CRC32 Checksum (CRC32Coder)	216
10.15	CRC-CCITT Checksum (CCITTCoder)	216
10.16	Adler32 Checksum (Adler32Coder)	216
10.17	MD5 Checksum (MD5SumCoder)	217
10.18	SHA-1 Checksum (SHACoder)	217
10.19	Encoding Output Stream (encoding_ostream)	218
10.20	Decoding Input Stream (decoding_istream)	218
10.21	Encoding File Stream (encoding_ofstream)	219
10.22	Decoding File Stream (decoding_ifstream)	220
10.23	Coder Pipes (CoderPipe2)	222
10.24	Automatic Decoder (AutoDecoder)	225
10.25	Block Coder (BlockCoder)	227
10.26	Memory Streambuffer (memory_streambuf)	231

11 Symmetric Key Cryptography	233
11.1 Secure Byte String (<code>CryptByteString</code>)	238
11.2 Key for Cryptography (<code>CryptKey</code>)	239
11.3 Encryption and Decryption with Ciphers	242
11.4 Example for a Stream-Cipher (<code>CBCCoder</code>)	244
11.5 Authentication (<code>OMACCoder</code>)	247
11.6 Automatic Decoder supporting Cryptography (<code>CryptAutoDecoder</code>)	250
11.7 Secure Socket Streambuffer (<code>secure_socket_streambuf</code>)	253
12 Graphs and Related Data Types	257
12.1 Graphs (<code>graph</code>)	257
12.2 Parameterized Graphs (<code>GRAPH</code>)	273
12.3 Static Graphs (<code>static_graph</code>)	277
12.4 Undirected Graphs (<code>ugraph</code>)	283
12.5 Parameterized Ugraph (<code>UGRAPH</code>)	283
12.6 Planar Maps (<code>planar_map</code>)	285
12.7 Parameterized Planar Maps (<code>PLANAR_MAP</code>)	287
12.8 Node Arrays (<code>node_array</code>)	289
12.9 Edge Arrays (<code>edge_array</code>)	291
12.10 Face Arrays (<code>face_array</code>)	293
12.11 Node Maps (<code>node_map</code>)	295
12.12 Edge Maps (<code>edge_map</code>)	297
12.13 Face Maps (<code>face_map</code>)	299
12.14 Two Dimensional Node Arrays (<code>node_matrix</code>)	301
12.15 Two-Dimensional Node Maps (<code>node_map2</code>)	303
12.16 Sets of Nodes (<code>node_set</code>)	305
12.17 Sets of Edges (<code>edge_set</code>)	306
12.18 Lists of Nodes (<code>node_list</code>)	307
12.19 Node Partitions (<code>node_partition</code>)	309
12.20 Node Priority Queues (<code>node_pq</code>)	310
12.21 Bounded Node Priority Queues (<code>b_node_pq</code>)	312
12.22 Graph Generators (<code>graph_gen</code>)	314
12.23 Miscellaneous Graph Functions (<code>graph_misc</code>)	319
12.24 Markov Chains (<code>markov_chain</code>)	323
12.25 Dynamic Markov Chains (<code>dynamic_markov_chain</code>)	324
12.26 GML Parser for Graphs (<code>gml_graph</code>)	325
12.27 The LEDA graph input/output format	330

13 Graph Algorithms	331
13.1 Basic Graph Algorithms (<code>basic_graph_alg</code>)	332
13.2 Shortest Path Algorithms (<code>shortest_path</code>)	335
13.3 Maximum Flow (<code>max_flow</code>)	339
13.4 Min Cost Flow Algorithms (<code>min_cost_flow</code>)	341
13.5 Minimum Cut (<code>min_cut</code>)	342
13.6 Maximum Cardinality Matchings in Bipartite Graphs (<code>mcb_matching</code>) . .	344
13.7 Bipartite Weighted Matchings and Assignments (<code>mwb_matching</code>)	345
13.8 Maximum Cardinality Matchings in General Graphs (<code>mc_matching</code>) . . .	349
13.9 General Weighted Matchings (<code>mw_matching</code>)	350
13.10 Stable Matching (<code>stable_matching</code>)	357
13.11 Minimum Spanning Trees (<code>min_span</code>)	359
13.12 Euler Tours (<code>euler_tour</code>)	360
13.13 Algorithms for Planar Graphs (<code>plane_graph_alg</code>)	361
13.14 Graph Drawing Algorithms (<code>graph_draw</code>)	364
13.15 Graph Morphism Algorithms (<code>graph_morphism</code>)	367
13.16 Graph Morphism Algorithm Functionality (<code>graph_morphism_algorithm</code>) .	368
14 Graphs and Iterators	375
14.1 Introduction	375
14.1.1 Iterators	375
14.1.2 Handles and Iterators	376
14.1.3 STL Iterators	376
14.1.4 Circulators	377
14.1.5 Data Accessors	377
14.1.6 Graphiterator Algorithms	379
14.2 Node Iterators (<code>NodeIt</code>)	381
14.3 Edge Iterators (<code>EdgeIt</code>)	383
14.4 Face Iterators (<code>FaceIt</code>)	384
14.5 Adjacency Iterators for leaving edges (<code>OutAdjIt</code>)	386
14.6 Adjacency Iterators for incoming edges (<code>InAdjIt</code>)	389
14.7 Adjacency Iterators (<code>AdjIt</code>)	391
14.8 Face Circulators (<code>FaceCirc</code>)	394
14.9 Filter Node Iterator (<code>FilterNodeIt</code>)	396
14.10 Comparison Predicate (<code>CompPred</code>)	397
14.11 Observer Node Iterator (<code>ObserverNodeIt</code>)	399

14.12	STL Iterator Wrapper (STLNodeIt)	401
14.13	Node Array Data Accessor (node_array_da)	403
14.14	Constant Accessors (constant_da)	405
14.15	Node Member Accessors (node_member_da)	405
14.16	Node Attribute Accessors (node_attribute_da)	407
14.17	Breadth First Search (flexible) (GIT_BFS)	408
14.18	Depth First Search (flexible) (GIT_DFS)	410
14.19	Topological Sort (flexible) (GIT_TOPOSORT)	412
14.20	Strongly Connected Components (flexible) (GIT_SCC)	414
14.21	Dijkstra(flexible) (GIT_DIJKSTRA)	416
15	Basic Data Types for Two-Dimensional Geometry	419
15.1	Points (point)	420
15.2	Segments (segment)	425
15.3	Straight Rays (ray)	429
15.4	Straight Lines (line)	432
15.5	Circles (circle)	436
15.6	Polygons (POLYGON)	440
15.7	Generalized Polygons (GEN_POLYGON)	446
15.8	Triangles (triangle)	453
15.9	Iso-oriented Rectangles (rectangle)	456
15.10	Rational Points (rat_point)	459
15.11	Rational Segments (rat_segment)	464
15.12	Rational Rays (rat_ray)	469
15.13	Straight Rational Lines (rat_line)	472
15.14	Rational Circles (rat_circle)	476
15.15	Rational Triangles (rat_triangle)	479
15.16	Iso-oriented Rational Rectangles (rat_rectangle)	482
15.17	Real Points (real_point)	486
15.18	Real Segments (real_segment)	491
15.19	Real Rays (real_ray)	495
15.20	Straight Real Lines (real_line)	498
15.21	Real Circles (real_circle)	502
15.22	Real Triangles (real_triangle)	506
15.23	Iso-oriented Real Rectangles (real_rectangle)	509
15.24	Geometry Algorithms (geo_alg)	513
15.25	Transformation (TRANSFORM)	524
15.26	Point Generators (point generators)	527
15.27	Point on Rational Circle (r_circle_point)	531
15.28	Segment of Rational Circle (r_circle_segment)	533
15.29	Polygons with circular edges (r_circle_polygon)	538
15.30	Generalized polygons with circular edges (r_circle_gen_polygon)	544
15.31	Parser for well known binary format (wkb_io)	552

16 Advanced Data Types for Two-Dimensional Geometry	553
16.1 Two-Dimensional Dictionaries (<code>d2_dictionary</code>)	553
16.2 Point Sets and Delaunay Triangulations (<code>POINT_SET</code>)	556
16.3 Point Location in Triangulations (<code>POINT_LOCATOR</code>)	562
16.4 Sets of Intervals (<code>interval_set</code>)	563
16.5 Sets of Parallel Segments (<code>segment_set</code>)	565
16.6 Sets of Parallel Rational Segments (<code>rat_segment_set</code>)	567
16.7 Planar Subdivisions (<code>subdivision</code>)	569
17 Basic Data Types for Three-Dimensional Geometry	571
17.1 Points in 3D-Space (<code>d3_point</code>)	572
17.2 Straight Rays in 3D-Space (<code>d3_ray</code>)	577
17.3 Segments in 3D-Space (<code>d3_segment</code>)	579
17.4 Straight Lines in 3D-Space (<code>d3_line</code>)	581
17.5 Planes (<code>d3_plane</code>)	583
17.6 Spheres in 3D-Space (<code>d3_sphere</code>)	586
17.7 Simplices in 3D-Space (<code>d3_simplex</code>)	588
17.8 Rational Points in 3D-Space (<code>d3_rat_point</code>)	590
17.9 Straight Rational Rays in 3D-Space (<code>d3_rat_ray</code>)	599
17.10 Rational Lines in 3D-Space (<code>d3_rat_line</code>)	601
17.11 Rational Segments in 3D-Space (<code>d3_rat_segment</code>)	604
17.12 Rational Planes (<code>d3_rat_plane</code>)	607
17.13 Rational Spheres (<code>d3_rat_sphere</code>)	610
17.14 Rational Simplices (<code>d3_rat_simplex</code>)	612
17.15 3D Convex Hull Algorithms (<code>d3_hull</code>)	614
17.16 3D Triangulation and Voronoi Diagram Algorithms (<code>d3_delaunay</code>)	615
18 Graphics	617
18.1 Colors (<code>color</code>)	617
18.2 Windows (<code>window</code>)	619

Chapter 1

Preface

One of the major differences between combinatorial computing and other areas of computing such as statistics, numerical analysis and linear programming is the use of complex data types. Whilst the built-in types, such as integers, reals, vectors, and matrices, usually suffice in the other areas, combinatorial computing relies heavily on types like stacks, queues, dictionaries, sequences, sorted sequences, priority queues, graphs, points, segments, . . . In the fall of 1988, we started a project (called **LEDA** for Library of Efficient Data types and Algorithms) to build a small, but growing library of data types and algorithms in a form which allows them to be used by non-experts. We hope that the system will narrow the gap between algorithms research, teaching, and implementation. The main features of LEDA are:

1. LEDA provides a sizable collection of data types and algorithms in a form which allows them to be used by non-experts. This collection includes most of the data types and algorithms described in the text books of the area.
2. LEDA gives a precise and readable specification for each of the data types and algorithms mentioned above. The specifications are short (typically, not more than a page), general (so as to allow several implementations), and abstract (so as to hide all details of the implementation).
3. For many efficient data structures access by position is important. In LEDA, we use an item concept to cast positions into an abstract form. We mention that most of the specifications given in the LEDA manual use this concept, i.e., the concept is adequate for the description of many data types.
4. LEDA contains efficient implementations for each of the data types, e.g., Fibonacci heaps for priority queues, skip lists and dynamic perfect hashing for dictionaries, ...
5. LEDA contains a comfortable data type graph. It offers the standard iterations such as “for all nodes v of a graph G do” or “for all neighbors w of v do”, it allows to add and delete vertices and edges and it offers arrays and matrices indexed by nodes and edges,... The data type graph allows to write programs for graph problems in a form close to the typical text book presentation.
6. LEDA is implemented by a C++ class library. It can be used with almost any C++ compiler that supports templates.

7. LEDA is available from Algorithmic Solutions Software GmbH. See <http://www.algorithmic-solutions.com>.

This manual contains the specifications of all data types and algorithms currently available in LEDA. Users should be familiar with the C++ programming language (see [83] or [56]).

The manual is structured as follows: In Chapter Basics, which is a prerequisite for all other chapters, we discuss the basic concepts and notations used in LEDA. New users of LEDA should carefully read Section User Defined Parameter Types to avoid problems when plugging in self defined parameter types. If you want to get information about the LEDA documentation scheme please read Section DocTools. For technical information concerning the installation and usage of LEDA users should refer to Chapter TechnicalInformation. There is also a section describing namespaces and the interaction with other software libraries (Section NameSpace). The other chapters define the data types and algorithms available in LEDA and give examples of their use. These chapters can be consulted independently from one another.

More information about LEDA can be found on the LEDA web page:
<http://www.algorithmic-solutions.com/leda/>

Finally there's a tool called `xlman` which allows online help and demonstration on all unix platforms having a \LaTeX package installed.

New in Version 6.6.1

Please read the CHANGES and FIXES files in the LEDA root directory for more information.

Chapter 2

Basics

An extended version of this chapter is available as chapter Foundations of [64]

2.1 Getting Started

Please use your favourite text editor to create a file *prog.c* with the following program:

```
#include <LEDA/core/d_array.h>
#include <LEDA/core/string.h>
#include <iostream>

using std::cin;
using std::cout;
using std::endl;
using leda::string;
using leda::d_array;

int main()
{
    d_array<string,int> N(0);
    string s;
    while (cin >> s) N[s]++;
    forall_defined (s,N)
        cout << s << " " << N[s] << endl;

    return 0;
}
```

If you followed the installation guidelines (see Chapter TechnicalInformation ff.), you can compile and link it with LEDA's library *libleda* (cf. Section Libraries). For example, on a Unix machine where *g++* is installed you can type

```
g++ -o prog prog.c -lleda -lX11 -lm
```

When executed it reads a sequence of strings from the standard input and then prints the number of occurrences of each string on the standard output. More examples of LEDA programs can be found throughout this manual.

The program above uses the parameterized data type dictionary array (`d_array<I,E>`) from the library. This is expressed by the include statement (cf. Section Header Files for more details). The specification of the data type `d_array` can be found in Section Dictionary Arrays. We use it also as a running example to discuss the principles underlying LEDA in the following sections.

2.2 The LEDA Manual Page (the type specification)

In general the specification of a LEDA data type consists of five parts: a definition of the set of objects comprising the (parameterized) abstract data type, a list of all local types of the data type, a description of how to create an object of the data type, the definition of the operations available on the objects of the data type, and finally, information about the implementation. The five parts appear under the headers **definition**, **types**, **creation**, **operations**, and **implementation**, respectively. Sometimes there is also a fifth part showing an **example**.

- **Definition**

This part of the specification defines the objects (also called instances or elements) comprising the data type using standard mathematical concepts and notation.

Example

The generic data type dictionary array:

An object a of type `d_array<I,E>` is an injective function from the data type I to the set of variables of data type E . The types I and E are called the index and the element type, respectively. a is called a dictionary array from I to E .

Note that the types I and E are parameters in the definition above. Any built-in, pointer, item, or user-defined class type T can be used as actual type parameter of a parameterized data type. Class types however have to provide several operations listed in Chapter User Defined Parameter Types.

- **Types**

This section gives the list of all local types of the data type. For example,

```
d_array<I,E>::item           the item type.
d_array<I,E>::index_type    the index type.
d_array<I,E>::element_type  the element type.
```

- **Creation**

A variable of a data type is introduced by a C++ variable declaration. For all LEDA data types variables are initialized at the time of declaration. In many cases the user has to provide arguments used for the initialization of the variable. In general a declaration

```
XYZ<t1, ... ,tk> y(x1, ... ,xt);
```

introduces a variable y of the data type `XYZ< t1, ... ,tk >` and uses the arguments x_1, \dots, x_t to initialize it. For example,

```
h_array<string,int> A(0);
```

introduces A as a dictionary array from strings to integers, and initializes A as follows: an injective function a from *string* to the set of unused variables of type *int* is constructed, and is assigned to A . Moreover, all variables in the range of a are initialized to 0. The reader may wonder how LEDA handles an array of infinite size. The solution is, of course, that only that part of A is explicitly stored which has been accessed already.

For all data types, the assignment operator (`=`) is available for variables of that type. Note however that assignment is in general not a constant time operation, e.g., if L_1 and L_2 are variables of type `list<T>` then the assignment $L_1 = L_2$ takes time proportional to the length of the list L_2 times the time required for copying an object of type T .

Remark: For most of the complex data types of LEDA, e.g., dictionaries, lists, and priority queues, it is convenient to interpret a variable name as the name for an object of the data type which evolves over time by means of the operations applied to it. This is appropriate, whenever the operations on a data type only “modify” the values of variables, e.g., it is more natural to say an operation on a dictionary D modifies D than to say that it takes the old value of D , constructs a new dictionary out of it, and assigns the new value to D . Of course, both interpretations are equivalent. From this more object-oriented point of view, a variable declaration, e.g., `dictionary<string,int> D`, is creating a new dictionary object with name D rather than introducing a new variable of type `dictionary<string,int>`; hence the name “Creation” for this part of a specification.

• Operations

In this section the operations of the data types are described. For each operation the description consists of two parts

1. The interface of the operation is defined using the C++ function declaration syntax. In this syntax the result type of the operation (*void* if there is no result) is followed by the operation name and an argument list specifying the type of each argument. For example,

```
list_item L.insert (E x, list_item it, int dir = leda::after)
```

defines the interface of the insert operation on a list L of elements of type E (cf. Section Linear Lists). Insert takes as arguments an element x of type E , a *list_item* it and an optional relative position argument dir . It returns a *list_item* as result.

```
E& A[I x]
```

defines the interface of the access operation on a dictionary array A . It takes an element x of type I as an argument and returns a variable of type E .

2. The effect of the operation is defined. Often the arguments have to fulfill certain preconditions. If such a condition is violated the effect of the operation is undefined. Some, but not all, of these cases result in error messages and abnormal termination of the program (see also Section Error Handling). For the insert operation on lists this definition reads:

A new item with contents x is inserted after (if $dir = leda::after$) or before (if $dir = leda::before$) item it into L . The new item is returned.
Precondition: item it must be in L .

For the access operation on dictionary arrays the definition reads:

returns the variable $A(x)$.

• Implementation

The implementation section lists the (default) data structures used to implement the data type and gives the time bounds for the operations and the space requirement. For example,

Dictionary arrays are implemented by randomized search trees ([2]). Access operations $A[x]$ take time $O(\log \text{dom}(A))$. The space requirement is $O(\text{dom}(A))$.

2.3 User Defined Parameter Types

If a user defined class type T shall be used as actual type parameter in a container class, it has to provide the following operations:

- | | |
|--------------------------------------|---|
| a) a constructor taking no arguments | $T :: T()$ |
| b) a copy constructor | $T :: T(const T\&)$ |
| c) an assignment operator | $T\& T :: \mathbf{operator} = (const T\&)$ |
| d) an input operator | $istream\& \mathbf{operator} >> (istream\&, T\&)$ |
| e) an output operator | $ostream\& \mathbf{operator} << (ostream\&, const T\&)$ |

and if required by the parameterized data type

- | | |
|-----------------------|--|
| f) a compare function | $int \mathbf{compare}(const T\&, const T\&)$ |
| g) a hash function | $int \mathbf{Hash}(const T\&)$ |

Notice: Starting with version 4.4 of LEDA, the operations "compare" and "Hash" for a user defined type need to be defined inside the "namespace leda"!

In the following two subsections we explain the background of the required compare and hash function. Section Implementation Parameters concerns a very special parameter type, namely implementation parameters.

2.3.1 Linear Orders

Many data types, such as dictionaries, priority queues, and sorted sequences require linearly ordered parameter types. Whenever a type T is used in such a situation, e.g. in `dictionary<T, ...>` the function

```
int compare(const T&, const T&)
```

must be declared and must define a linear order on the data type T .

A binary relation rel on a set T is called a linear order on T if for all x, y, z in T :

- 1) $x rel x$
- 2) $x rel y$ and $y rel z$ implies $x rel z$
- 3) $x rel y$ or $y rel x$
- 4) $x rel y$ and $y rel x$ implies $x = y$

A function `int compare(const T&, const T&)` defines the linear order rel on T if

$$\text{compare}(x, y) \begin{cases} < 0, & \text{if } x rel y \text{ and } x \neq y \\ = 0, & \text{if } x = y \\ > 0, & \text{if } y rel x \text{ and } x \neq y \end{cases}$$

For each of the data types *char*, *short*, *int*, *long*, *float*, *double*, *integer*, *rational*, *bigfloat*, *real*, *string*, and *point* a function *compare* is predefined and defines the so-called default ordering on that type. The default ordering is the usual \leq - order for the built-in numerical types, the lexicographic ordering for *string*, and for *point* the lexicographic ordering of the cartesian coordinates. For all other types T there is no default ordering, and the user has to provide a *compare* function whenever a linear order on T is required.

Example: Suppose pairs of double numbers shall be used as keys in a dictionary with the lexicographic order of their components. First we declare class *pair* as the type of pairs of double numbers, then we define the I/O operations *operator>>* and *operator<<* and the lexicographic order on *pair* by writing an appropriate *compare* function.

```
class pair {
    double x;
    double y;

public:
    pair() { x = y = 0; }
    pair(const pair& p) { x = p.x; y = p.y; }
    pair& operator=(const pair& p)
    {
        if(this != &p)
            { x = p.x; y = p.y; }
        return *this;
    }
}
```

```

double get_x() {return x;}
double get_y() {return y;}

friend istream& operator>> (istream& is, pair& p)
{ is >> p.x >> p.y; return is; }
friend ostream& operator<< (ostream& os, const pair& p)
{ os << p.x << " " << p.y; return os; }
};

namespace leda {
int compare(const pair& p, const pair& q)
{
    if (p.get_x() < q.get_x()) return -1;
    if (p.get_x() > q.get_x()) return 1;
    if (p.get_y() < q.get_y()) return -1;
    if (p.get_y() > q.get_y()) return 1;
    return 0;
}
};

```

Now we can use dictionaries with key type *pair*, e.g.,

```
dictionary<pair,int> D;
```

Sometimes, a user may need additional linear orders on a data type T which are different from the order defined by *compare*. In the following example a user wants to order points in the plane by the lexicographic ordering of their cartesian coordinates and by their polar coordinates. The former ordering is the default ordering for points. The user can introduce an alternative ordering on the data type *point* (cf. Section Basic Data Types for Two-Dimensional Geometry) by defining an appropriate compare function (in namespace *leda*)

```
int pol_cmp(const point& x, const point& y)
{ /* lexicographic ordering on polar coordinates */ }
```

Now she has several possibilities:

1. First she can call the macro

```
DEFINE_LINEAR_ORDER(point, pol_cmp, pol_point)
```

After this call *pol_point* is a new data type which is equivalent to the data type *point*, with the only exception that if *pol_point* is used as an actual parameter e.g. in `dictionary<pol_point, ...>`, the resulting data type is based on the linear order defined by *pol_cmp*. Now, dictionaries based on either ordering can be used.

```
dictionary<point,int>    D0; // default ordering
dictionary<pol_point,int> D1; // polar ordering
```

In general the macro call

```
DEFINE_LINEAR_ORDER(T, cmp, T1)
```

introduces a new type $T1$ equivalent to type T with the linear order defined by the compare function cmp .

2. As a new feature all order based data types like dictionaries, priority queues, and sorted sequences offer a constructor which allows a user to set the internally used ordering at construction time.

```
dictionary<point,int> D0;           // default ordering
dictionary<point,int> D1(pol_cmp); // polar ordering
```

This alternative handles the cases where two or more different orderings are needed more elegantly.

3. Instead of passing a compare function $cmp(const T\&, const T\&)$ to the sorted type one can also pass an object (a so-called *compare object*) of a class that is derived from the class *leda_cmp_base* and that overloads the function-call operator $int operator()(const T\&, const T\&)$ to define a linear order for T .

This variant is helpful when the compare function depends on a global parameter. We give an example. More examples can be found in several sections of the LEDA book [64]. Assume that we want to compare edges of a graph $GRAPH < point, int >$ (in this type every node has an associated point in the plane; the point associated with a node v is accessed as $G[v]$) according to the distance of their endpoints. We write

```
using namespace leda;

class cmp_edges_by_length: public leda_cmp_base<edge> {
    const GRAPH<point,int>& G;
public:
    cmp_edges_by_length(const GRAPH<point,int>& g): G(g){}

    int operator()(const edge& e, const edge& f) const
    { point pe = G[G.source(e)]; point qe = G[G.target(e)];
      point pf = G[G.source(f)]; point qf = G[G.target(f)];
      return compare(pe.sqr_dist(qe),pf.sqr_dist(qf));
    }
};

int main(){
    GRAPH<point,int> G;
```

```

    cmp_edges_by_length cmp(G);
    list<edge> E = G.all_edges();
    E.sort(cmp);

    return 0;
}

```

The class *cmp_edges_by_length* has a function operator that takes two edges e and f of a graph G and compares them according to their length. The graph G is a parameter of the constructor. In the main program we define $cmp(G)$ as an instance of *cmp_edges_by_length* and then pass cmp as the compare object to the sort function of `list<edge>`. In the implementation of the sort function a comparison between two edges is made by writing $cmp(e, f)$, i.e., for the body of the sort function there is no difference whether a function or a compare object is passed to it.

2.3.2 Hashed Types

LEDA also contains parameterized data types requiring a *hash function* and an *equality test* (operator`==`) for the actual type parameters. Examples are dictionaries implemented by hashing with chaining (`dictionary<K,I,ch_hashing>`) or hashing arrays (`h_array<I,E>`). Whenever a type T is used in such a context, e.g., in `h_array<T, ...>` there must be defined

1. a hash function *int* **Hash**(*const T&*)
2. the equality test *bool* **operator** `==` (*const T&*, *const T&*)

Hash maps the elements of type T to integers. It is not required that *Hash* is a perfect hash function, i.e., it has not to be injective. However, the performance of the underlying implementations very strongly depends on the ability of the function to keep different elements of T apart by assigning them different integers. Typically, a search operation in a hashing implementation takes time linear in the maximal size of any subset whose elements are assigned the same hash value. For each of the simple numerical data types `char`, `short`, `int`, `long` there is a predefined *Hash* function: the identity function.

We demonstrate the use of *Hash* and a data type based on hashing by extending the example from the previous section. Suppose we want to associate information with values of the *pair* class by using a hashing array `h_array<pair,int>` A . We first define a hash function that assigns each pair (x, y) the integral part of the first component x

```

namespace leda {
int Hash(const pair& p) { return int(p.get_x()); }
};

```

and then we can use a hashing array with index type *pair*

```

h_array<pair, int> A;

```

2.4 Arguments

- **Optional Arguments**

The trailing arguments in the argument list of an operation may be optional. If these trailing arguments are missing in a call of an operation the default argument values given in the specification are used. For example, if the relative position argument in the list insert operation is missing it is assumed to have the value *leda::after*, i.e., $L.insert(it, y)$ will insert the item y after item it into L .

- **Argument Passing**

There are two kinds of argument passing in C++, by value and by reference. An argument x of type *type* specified by “*type x*” in the argument list of an operation or user defined function will be passed by value, i.e., the operation or function is provided with a copy of x . The syntax for specifying an argument passed by reference is “*type& x*”. In this case the operation or function works directly on x (the variable x is passed not its value).

Passing by reference must always be used if the operation is to change the value of the argument. It should always be used for passing large objects such as lists, arrays, graphs and other LEDA data types to functions. Otherwise a complete copy of the actual argument is made, which takes time proportional to its size, whereas passing by reference always takes constant time.

- **Functions as Arguments**

Some operations take functions as arguments. For instance the bucket sort operation on lists requires a function which maps the elements of the list into an interval of integers. We use the C++ syntax to define the type of a function argument f :

```
T (*f)(T1, T2, ..., Tk)
```

declares f to be a function taking k arguments of the data types $T1, \dots, Tk$, respectively, and returning a result of type T , i.e,

$$f : T1 \times \dots \times Tk \longrightarrow T$$

2.5 Items

Many of the advanced data types in LEDA (dictionaries, priority queues, graphs, ...), are defined in terms of so-called items. An item is a container which can hold an object relevant for the data type. For example, in the case of dictionaries a *dic_item* contains a pair consisting of a key and an information. A general definition of items is given at the end of this section.

Remark: Item types are, like all other types, functions, constants, ..., defined in the "namespace leda" in LEDA-4.5.

We now discuss the role of items for the dictionary example in some detail. A popular specification of dictionaries defines a dictionary as a partial function from some type K to some other type I , or alternatively, as a set of pairs from $K \times I$, i.e., as the graph of the function. In an implementation each pair (k, i) in the dictionary is stored in some location of the memory. Efficiency dictates that the pair (k, i) cannot only be accessed through the key k but sometimes also through the location where it is stored, e.g., we might want to lookup the information i associated with key k (this involves a search in the data structure), then compute with the value i a new value i' , and finally associate the new value with k . This either involves another search in the data structure or, if the lookup returned the location where the pair (k, i) is stored, can be done by direct access. Of course, the second solution is more efficient and we therefore wanted to provide it in LEDA.

In LEDA items play the role of positions or locations in data structures. Thus an object of type `dictionary<K,I>`, where K and I are types, is defined as a collection of items (type `dic_item`) where each item contains a pair in $K \times I$. We use $\langle k, i \rangle$ to denote an item with key k and information i and require that for each k in K there is at most one i in I such that $\langle k, i \rangle$ is in the dictionary. In mathematical terms this definition may be rephrased as follows: A dictionary d is a partial function from the set `dic_item` to the set $K \times I$. Moreover, for each k in K there is at most one i in I such that the pair (k, i) is in d .

The functionality of the operations

```
dic_item D.lookup(K k)
I        D.inf(dic_item it)
void     D.change_inf(dic_item it, I i')
```

is now as follows: $D.lookup(K k)$ returns an item it with contents (k, i) , $D.inf(it)$ extracts i from it , and a new value i' can be associated with k by $D.change_inf(it, i')$.

Let us have a look at the insert operation for dictionaries next:

```
dic_item D.insert(K k, I i)
```

There are two cases to consider. If D contains an item it with contents (k, i') then i' is replaced by i and it is returned. If D contains no such item, then a new item, i.e., an item which is not contained in any dictionary, is added to D , this item is made to contain (k, i) and is returned. In this manual (cf. Section Dictionaries) all of this is abbreviated to

`dic_item D.insert(K k, I i)` associates the information i with the key k . If there is an item $\langle k, j \rangle$ in D then j is replaced by i , else a new item $\langle k, i \rangle$ is added to D . In both cases the item is returned.

We now turn to a general discussion. With some LEDA types XYZ there is an associated type `XYZ_item` of items. Nothing is known about the objects of type `XYZ_item` except that there are infinitely many of them. The only operations available on `XYZ_items` besides the one defined in the specification of type XYZ is the equality predicate “==”

and the assignment operator “=” . The objects of type XYZ are defined as sets or sequences of XYZ_items containing objects of some other type Z . In this situation an XYZ_item containing an object z in Z is denoted by $|z|_i$. A new or unused XYZ_item is any XYZ_item which is not part of any object of type XYZ .

Remark: For some readers it may be useful to interpret a dic_item as a pointer to a variable of type $K \times I$. The differences are that the assignment to the variable contained in a dic_item is restricted, e.g., the K -component cannot be changed, and that in return for this restriction the access to dic_items is more flexible than for ordinary variables, e.g., access through the value of the K -component is possible.

2.6 Iteration

For many (container) types LEDA provides iteration macros. These macros can be used to iterate over the elements of lists, sets and dictionaries or the nodes and edges of a graph. Iteration macros can be used similarly to the C++ **for** statement. Examples are

- for all item based data types:
 - `forall_items(it, D)` { the items of D are successively assigned to variable it }
 - `forall_rev_items(it, D)` { the items of D are assigned to it in reverse order }
- for lists and sets:
 - `forall(x, L)` { the elements of L are successively assigned to x }
 - `forall_rev(x, L)` { the elements of L are assigned to x in reverse order }
- for graphs:
 - `forall_nodes(v, G)` { the nodes of G are successively assigned to v }
 - `forall_edges(e, G)` { the edges of G are successively assigned to e }
 - `forall_adj_edges(e, v)` { all edges adjacent to v are successively assigned to e }

PLEASE NOTE:

Inside the body of a forall loop insertions into or deletions from the corresponding container are not allowed, with one exception, the current item or object of the iteration may be removed, as in

```
forall_edges(e,G) {
  if (source(e) == target(e)) G.del_edge(e);
} // remove self-loops
```

The item based data types `list`, `array`, and `dictionary` provide now also an STL compatible iteration scheme. The following example shows STL iteration on lists. Note that not all LEDA supported compilers allow the usage of this feature.

```
using namespace leda;
using std::cin;
using std::cout;
using std::endl;

list<int> L;
// fill list somehow
list<int>::iterator it;
for ( it = L.begin(); it != L.end(); it++ )
    cout << *it << endl;
```

`list<int>::iterator` defines the iterator type, `begin()` delivers access to the first list item via an iterator. `end()` is the past the end iterator and serves as an end marker. The increment operator `++` moves the iterator one position to the next item, and `*it` delivers the content of the item to which the iterator is pointing. For more information on STL please refer to the standard literature about STL.

For a more flexible access to the LEDA graph data type there are graph iterators which extent the STL paradigm to more complex container types. To make use of these features please refer to Graph Iterators.

Chapter 3

Modules

During the last years, LEDA's main include directory has grown to more than 400 include files. As a result, the include directory was simply too complex so that new features were hard to identify. We therefore introduced modules to better organize LEDA's include structure. Starting from version 5.0 LEDA consists of the several modules:

- *core* (LEDA/incl/core/) Module core stores all basic data types (array, list, set, partition, etc.), all dictionary types (dictionary, d_array, h_array sortseq, etc.), all priority queues, and basic algorithms like sorting.
- *numbers* (LEDA/incl/numbers/) Module numbers stores all LEDA number types (integer, real, rational, bigfloat, polynomial, etc.) as well as data types related to linear algebra (vector, matrix, etc.) and all additional data types and functions related to numerical computation (fpu, numerical analysis, etc.)
- *graph* (LEDA/incl/graph/) Module graph stores all graph data types, all types related to graphs and all graph algorithms.
- *geo* (LEDA/incl/geo/) Module geo stores all geometric data types and all geometric algorithms.
- *graphics* (LEDA/incl/graphics/) Module graphics stores all include files and data types related to our graphical user interfaces, i.e. window, graphwin and geowin.
- *coding* (LEDA/incl/coding/) Module codings contains all data types and algorithms relating to compression and cryptography.
- *system* (LEDA/incl/system/) Module system contains all data types that offer system-related functionality like date, time, stream, error handling and memory management.

- *internal* (LEDA/incl/internal/)
Module *internal* contains include files that are needed for LEDA's maintenance or for people who want to implement extension packages.
- *beta* (LEDA/incl/beta/)
Module *beta* contains data types that are not fully tested.
- *exp* (LEDA/incl/exp/)
Module *exp* contains data types that are experimental. Most of these data types can be used as implementation parameters for the data types dictionary, priority queues, *d.array*, and *sortseq*. Starting with LEDA version 6.5, experimental data types are no longer available in pre-compiled object code packages.

Chapter 4

Simple Data Types and Basic Support Operations

This section describes simple data types like strings, streams and gives some information about error handling, memory management and file system access. The stream data types described in this section are all derived from the C++ stream types *istream* and *ostream*. They can be used in any program that includes the `<LEDA/stream.h>` header file. Some of these types may be obsolete in combination with the latest versions of the standard C++ I/O library.

4.1 Strings (`string`)

1. Definition

An instance *s* of the data type *string* is a sequence of characters (type *char*). The number of characters in the sequence is called the length of *s*. A string of length zero is called the empty string. Strings can be used wherever a C++ `const char*` string can be used.

Strings differ from the C++ type `char*` in several aspects: parameter passing by value and assignment works properly (i.e., the value is passed or assigned and not a pointer to the value) and *strings* offer many additional operations.

```
#include < LEDA/core/string.h >
```

2. Types

`string::size_type` the size type.

3. Creation

`string s;` introduces a variable *s* of type *string*. *s* is initialized with the empty string.

- string* $s(\text{const char} * p)$; introduces a variable s of type *string*. s is initialized with a copy of the C++ string p .
- string* $s(\text{char } c)$; introduces a variable s of type *string*. s is initialized with the one-character string “ c ”.
- string* $s(\text{const char} * \text{format}, \dots)$; introduces a variable s of type *string*. s is initialized with the string produced by `printf(format, ...)`.

4. Operations

- int* $s.\text{length}()$ returns the length of string s .
- bool* $s.\text{empty}()$ returns whether s is the empty string.
- char* $s.\text{get}(\text{int } i)$ returns the character at position i .
Precondition: $0 \leq i \leq s.\text{length}()-1$.
- char&* $s[\text{int } i]$ returns a reference to the character at position i .
Precondition: $0 \leq i \leq s.\text{length}()-1$.
- string* $s.\text{substring}(\text{int } i, \text{int } j)$ returns the substring of s starting at position $\max(0, i)$ and ending at position $\min(j - 1, s.\text{length}()-1)$.
- string* $s.\text{substring}(\text{int } i)$ returns the substring of s starting at position $\max(0, i)$.
- string* $s(\text{int } i, \text{int } j)$ returns the substring of s starting at position $\max(0, i)$ and ending at position $\min(j, s.\text{length}()-1)$.
If $\min(j, s.\text{length}()-1) < \max(0, i)$ then the empty string is returned.
- string* $s.\text{head}(\text{int } i)$ returns the first i characters of s if $i \geq 0$ and the first $(\text{length}() + i)$ characters of s if $i < 0$.
- string* $s.\text{tail}(\text{int } i)$ returns the last i characters of s if $i \geq 0$ and the last $(\text{length}() + i)$ characters of s if $i < 0$.
- int* $s.\text{pos}(\text{string } s1, \text{int } i)$ returns the minimum j such that $j \geq i$ and s_1 is a substring of s starting at position j (returns -1 if no such j exists).
- int* $s.\text{pos}(\text{const string\& } s1)$ returns `pos(s1, 0)`.
- bool* $s.\text{contains}(\text{const string\& } s1)$
true iff $s1$ is a substring of s .

<i>bool</i>	<code>s.starts_with(const string& s1)</code>	true iff <i>s</i> starts with <i>s1</i> .
<i>bool</i>	<code>s.ends_with(const string& s1)</code>	true iff <i>s</i> ends with <i>s1</i> .
<i>string</i>	<code>s.insert(int i, string s1)</code>	returns $s(0, i - 1) + s_1 + s(i, s.length() - 1)$.
<i>string</i>	<code>s.replace(const string& s1, const string& s2, int i = 1)</code>	returns the string created from <i>s</i> by replacing the <i>i</i> -th occurrence of <i>s1</i> in <i>s</i> by <i>s2</i> . Remark: The occurrences of <i>s1</i> in <i>s</i> are counted in a non-overlapping manner, for instance the string <i>sasas</i> contains only one occurrence of the string <i>sas</i> .
<i>string</i>	<code>s.replace(int i, int j, const string& s1)</code>	returns the string created from <i>s</i> by replacing $s(i, j)$ by <i>s1</i> . Precondition: $i \leq j$.
<i>string</i>	<code>s.replace(int i, const string& s1)</code>	returns the string created from <i>s</i> by replacing $s[i]$ by <i>s1</i> .
<i>string</i>	<code>s.replace_all(const string& s1, const string& s2)</code>	returns the string created from <i>s</i> by replacing all occurrences of <i>s1</i> in <i>s</i> by <i>s2</i> . Precondition: The occurrences of <i>s1</i> in <i>s</i> do not overlap (it's hard to say what the function returns if the precondition is violated.).
<i>string</i>	<code>s.del(const string& s1, int i = 1)</code>	returns <code>s.replace(s1, "", i)</code> .
<i>string</i>	<code>s.del(int i, int j)</code>	returns <code>s.replace(i, j, "")</code> .
<i>string</i>	<code>s.del(int i)</code>	returns <code>s.replace(i, "")</code> .
<i>string</i>	<code>s.delAll(const string& s1)</code>	returns <code>s.replace_all(s1, "")</code> .
<i>void</i>	<code>s.read(istream& I, char delim = '')</code>	reads characters from input stream <i>I</i> into <i>s</i> until the first occurrence of character <i>delim</i> . (If <i>delim</i> is <code>'\n'</code> it is extracted from the stream, otherwise it remains there.)
<i>void</i>	<code>s.read(char delim = '')</code>	same as <code>s.read(cin, delim)</code> .

<i>void</i>	<code>s.readline(istream& I)</code>	same as <code>s.read(I, '\n')</code> .
<i>void</i>	<code>s.readline()</code>	same as <code>s.readline(cin)</code> .
<i>void</i>	<code>s.read_file(istream& I)</code>	same as <code>s.read(I, 'EOF')</code> .
<i>void</i>	<code>s.read_file()</code>	same as <code>s.read_file(cin)</code> .
<i>string&</i>	<code>s += const string& x</code>	appends <code>x</code> to <code>s</code> and returns a reference to <code>s</code> .
<i>string</i>	<code>const string& x + const string& y</code>	returns the concatenation of <code>x</code> and <code>y</code> .
<i>bool</i>	<code>const string& x == const string& y</code>	true iff <code>x</code> and <code>y</code> are equal.
<i>bool</i>	<code>const string& x != const string& y</code>	true iff <code>x</code> and <code>y</code> are not equal.
<i>bool</i>	<code>const string& x < const string& y</code>	true iff <code>x</code> is lexicographically smaller than <code>y</code> .
<i>bool</i>	<code>const string& x > const string& y</code>	true iff <code>x</code> is lexicographically greater than <code>y</code> .
<i>bool</i>	<code>const string& x ≤ const string& y</code>	returns <code>(x < y) (x == y)</code> .
<i>bool</i>	<code>const string& x ≥ const string& y</code>	returns <code>(x > y) (x == y)</code> .
<i>istream&</i>	<code>istream& I >> string& s</code>	same as <code>s.read(I, '')</code> .
<i>ostream&</i>	<code>ostream& O << const string& s</code>	writes string <code>s</code> to the output stream <code>O</code> .

5. Implementation

Strings are implemented by C++ character vectors. All operations involving the search for a pattern `s1` in a string `s` take time $O(s.length() * s1.length())$, `[]` takes constant time and all other operations on a string `s` take time $O(s.length())$.

4.2 File Input Streams (file_istream)

1. Definition

The data type *file_istream* is equivalent to the *ifstream* type of C++.

```
#include < LEDA/system/stream.h >
```

4.3 File Output Streams (file_ostream)

1. Definition

The data type *file_ostream* is equivalent to the *ofstream* type of C++.

```
#include < LEDA/system/stream.h >
```

4.4 String Input Streams (string_istream)

1. Definition

An instance *I* of the data type *string_istream* is an C++istream connected to a string *s*, i.e., all input operations or operators applied to *I* read from *s*.

```
#include < LEDA/system/stream.h >
```

2. Creation

```
string_istream I(const char * s);
```

creates an instance *I* of type *string_istream* connected to the string *s*.

3. Operations

All operations and operators (>>) defined for C++istreams can be applied to string input streams as well.

4.5 String Output Streams (string_ostream)

1. Definition

An instance *O* of the data type *string_ostream* is an C++ostream connected to an internal

string buffer, i.e., all output operations or operators applied to O write into this internal buffer. The current value of the buffer is called the contents of O .

```
#include < LEDA/system/stream.h >
```

2. Creation

string_ostream O ; creates an instance O of type *string_ostream*.

3. Operations

string $O.str()$ returns the current contents of O .

All operations and operators ($<<$) defined for C++ostreams can be applied to string output streams as well.

4.6 Random Sources (random_source)

1. Definition

An instance of type *random_source* is a random source. It allows to generate uniformly distributed random bits, characters, integers, and doubles. It can be in either of two modes: In bit mode it generates a random bit string of some given length p ($1 \leq p \leq 31$) and in integer mode it generates a random integer in some given range $[low..high]$ ($low \leq high < low + 2^{31}$). The mode can be changed any time, either globally or for a single operation. The output of the random source can be converted to a number of formats (using standard conversions).

```
#include < LEDA/core/random_source.h >
```

2. Creation

random_source S ; creates an instance S of type *random_source*, puts it into bit mode, and sets the precision to 31.

random_source $S(int\ p)$;
 creates an instance S of type *random_source*, puts it into bit mode, and sets the precision to p ($1 \leq p \leq 31$).

random_source $S(int\ low, int\ high)$;
 creates an instance S of type *random_source*, puts it into integer mode, and sets the range to $[low..high]$.

3. Operations

unsigned long $S.get()$ returns a random unsigned long integer (32 bits on 32-bit systems or on LLP64 systems and 64 bits on other 64-bit systems).

void $S.set_seed(int\ s)$ resets the seed of the random number generator to s .

int $S.reinit_seed()$ generates and sets a new seed s . The return value is s .

void $S.set_range(int\ low, int\ high)$ sets the mode to integer mode and changes the range to $[low..high]$.

int $S.set_precision(int\ p)$ sets the mode to bit mode, changes the precision to p bits and returns previous precision.

int $S.get_precision()$ returns current precision of S .

<i>random_source</i> & <i>S</i> >> <i>char</i> & <i>x</i>	extracts a character <i>x</i> of default precision or range and returns <i>S</i> , i.e., it first generates an unsigned integer of the desired precision or in the desired range and then converts it to a character (by standard conversion).
<i>random_source</i> & <i>S</i> >> <i>unsigned char</i> & <i>x</i>	extracts an unsigned character <i>x</i> of default precision or range and returns <i>S</i> .
<i>random_source</i> & <i>S</i> >> <i>int</i> & <i>x</i>	extracts an integer <i>x</i> of default precision or range and returns <i>S</i> .
<i>random_source</i> & <i>S</i> >> <i>long</i> & <i>x</i>	extracts a long integer <i>x</i> of default precision or range and returns <i>S</i> .
<i>random_source</i> & <i>S</i> >> <i>unsigned int</i> & <i>x</i>	extracts an unsigned integer <i>x</i> of default precision or range and returns <i>S</i> .
<i>random_source</i> & <i>S</i> >> <i>unsigned long</i> & <i>x</i>	extracts a long unsigned integer <i>x</i> of default precision or range and returns <i>S</i> .
<i>random_source</i> & <i>S</i> >> <i>double</i> & <i>x</i>	extracts a double precision floating point number <i>x</i> in $[0, 1]$, i.e. $u/(2^{31} - 1)$ where <i>u</i> is a random integer in $[0..2^{31} - 1]$, and returns <i>S</i> .
<i>random_source</i> & <i>S</i> >> <i>float</i> & <i>x</i>	extracts a single precision floating point number <i>x</i> in $[0, 1]$, i.e. $u/(2^{31} - 1)$ where <i>u</i> is a random integer in $[0..2^{31} - 1]$, and returns <i>S</i> .
<i>random_source</i> & <i>S</i> >> <i>bool</i> & <i>b</i>	extracts a random boolean value (true or false).
<i>int</i> <i>S</i> ()	returns an integer of default precision or range.
<i>int</i> <i>S</i> (<i>int prec</i>)	returns an integer of supplied precision <i>prec</i> .
<i>int</i> <i>S</i> (<i>int low</i> , <i>int high</i>)	returns an integer from the supplied range [<i>low</i> .. <i>high</i>].

4.7 Random Variates (random_variate)

1. Definition

An instance R of the data type *random_variate* is a non-uniform random number generator. The generation process is governed by an *array<int>* w . Let $[l..r]$ be the index range of w and let $W = \sum_i w[i]$ be the total weight. Then any integer $i \in [l..h]$ is generated with probability $w[i]/W$. The weight function w must be non-negative and W must be non-zero.

```
#include < LEDA/core/random_variate.h >
```

2. Creation

```
random_variate R(const array<int>& w);
```

creates an instance R of type *random_variate*.

3. Operations

```
int R.generate()
```

generates $i \in [l..h]$ with probability $w[i]/W$.

4.8 Dynamic Random Variates (dynamic_random_variate)

1. Definition

An instance R of the data type *dynamic_random_variate* is a non-uniform random number generator. The generation process is governed by an *array<int>* w . Let $[l..r]$ be the index range of w and let $W = \sum_i w[i]$ be the total weight. Then any integer $i \in [l..h]$ is generated with probability $w[i]/W$. The weight function w must be non-negative and W must be non-zero. The weight function can be changed dynamically.

```
#include < LEDA/core/random_variate.h >
```

2. Creation

```
dynamic_random_variate R(const array<int>& w);
```

creates an instance R of type *dynamic_random_variate*.

3. Operations

```
int R.generate()
```

generates $i \in [l..h]$ with probability $w[i]/W$.

int *R.set_weight(int i, int g)*

sets $w[i]$ to g and returns the old value of $w[i]$.

Precondition: $i \in [l..h]$.

4.9 Memory Management

LEDA offers an efficient memory management system that is used internally for all node, edge and item types. This system can easily be customized for user defined classes by the “LEDA_MEMORY” macro. You simply have to add the macro call “LEDA_MEMORY(*T*)” to the declaration of a class *T*. This redefines new and delete operators for type *T*, such that they allocate and deallocate memory using LEDA’s internal memory manager.

```
struct pair {
    double x;
    double y;

    pair() { x = y = 0; }
    pair(const pair& p) { x = p.x; y = p.y; }

    friend ostream& operator<<(ostream&, const pair&) { ... }
    friend istream& operator>>(istream&, pair&)      { ... }
    friend int compare(const pair& p, const pair& q) { ... }

    LEDA_MEMORY(pair)
};

dictionary<pair,int> D;
```

The LEDA memory manager only frees memory at its time of destruction (program end or unload of library) as this allows for much faster memory allocation requests. As a result, memory that was deallocated by a call to the redefined delete operator still resides in the LEDA memory management system and is not returned to the system memory manager. This might lead to memory shortages. To avoid those shortages, it is possible to return unused memory of LEDA’s memory management system to the system memory manager by calling

```
leda::std_memory_mgr.clear();
```

4.10 Memory Allocator (`leda_allocator`)

1. Definition

An instance A of the data type `leda_allocator<T>` is a memory allocator according to the C++ standard. `leda_allocator<T>` is the standard compliant interface to the LEDA memory management.

```
#include < LEDA/system/allocator.h >
```

2. Types

Local types are `size_type`, `difference_type`, `value_type`, `pointer`, `reference`, `const_pointer`, and `const_reference`.

```
template <class T1>
```

```
leda_allocator<T>::rebind allows the construction of a derived allocator:  
leda_allocator<T>::template rebind<T1>::other  
is the type leda_allocator<T1>.
```

3. Creation

```
leda_allocator<T> A; introduces a variable  $A$  of type leda_allocator<T>.
```

4. Operations

```
pointer      A.allocate(size_type n, const_pointer = 0)  
returns a pointer to a newly allocated memory range of  
size  $n * \text{sizeof}(T)$ .
```

```
void      A.deallocate(pointer p, size_type n)  
deallocates a memory range of  $n * \text{sizeof}(T)$  starting at  
 $p$ . Precondition: the memory range was obtained via  
allocate(n).
```

```
pointer      A.address(reference r)  
returns  $\&r$ .
```

```
const_pointer      A.address(const_reference r)  
returns  $\&r$ .
```

```
void      A.construct(pointer p, const_reference r)  
makes an inplace new new( (void*)p ) T(r).
```

```
void      A.destroy(pointer p)  
destroys the object referenced via  $p$  by calling  $p \rightarrow \sim T()$ .
```

size_type *A.max_size()* the largest value *n* for which the call *allocate(n, 0)* might succeed.

5. Implementation

Note that the above class template uses all kinds of modern compiler technology like member templates, partial specialization etc. It runs only on a subset of LEDA's general supported platforms like *g++ > 2.95*, *SGI CC > 7.3*.

4.11 Error Handling (`error`)

LEDA tests the preconditions of many (not all!) operations. Preconditions are never tested, if the test takes more than constant time. If the test of a precondition fails an error handling routine is called. It takes an integer error number i and a `char*` error message string s as arguments. The default error handler writes s to the diagnostic output (`cerr`) and terminates the program abnormally if $i \neq 0$. Users can provide their own error handling function *handler* by calling

```
set_error_handler(handler)
```

After this function call *handler* is used instead of the default error handler. *handler* must be a function of type `void handler(int, const char*)`. The parameters are replaced by the error number and the error message respectively.

New:

Starting with version 4.3 LEDA provides an *exception error handler*

```
void exception_error_handler(int num, const char * msg)
```

This handler uses the C++-exception mechanism and throws an exception of type `leda_exception` instead of terminating the program. An object of type `leda_exception` stores a pair consisting of an error number and an error message. Operations `e.get_msg()` and `e.get_num()` can be called to retrieve the corresponding values from an exception object e .

1. Operations

```
#include < LEDA/system/error.h >
```

```
void error_handler(int err_no, const char * msg)
```

reports error messages by passing `err_no` and `msg` to the default error handler.

```
LedaErrorHandler set_error_handler(void (*err_handler)(int, const char*))
```

sets the default error handler to function `err_handler`. Returns a pointer to the previous error handler.

```
LedaErrorHandler get_error_handler()
```

returns a pointer to the current default error handler.

```
void catch_system_errors(bool b = true)
```

after a call to this function system errors (e.g. bus errors and segmentation faults) are handled by LEDA's error handler.

bool `leda_assert(bool cond, const char * err_msg, int err_no = 0)`
 calls `error_handler(err_no, err_msg)` if *cond* =
 false and returns *cond*.

4.12 Files and Directories (file)

1. Operations

#include < LEDA/system/file.h >

- | | | |
|---------------------------|--|--|
| <i>string</i> | <code>set_directory(<i>string new_dir</i>)</code> | sets the current working directory to <i>new_dir</i> and returns the name of the old cwd. |
| <i>string</i> | <code>get_directory()</code> | returns the name of the current working directory. |
| <i>string</i> | <code>get_home_directory()</code> | returns the name of the user's home directory. |
| <i>string</i> | <code>get_directory_delimiter()</code> | returns the character that delimits directory names in a path (i.e. “\” on Windows and “/” on Unix). |
| <i>void</i> | <code>append_directory_delimiter(<i>string& dir</i>)</code> | appends the directory delimiter to <i>dir</i> if <i>dir</i> does not already end with the delimiter. |
| <i>void</i> | <code>remove_trailing_directory_delimiter(<i>string& dir</i>)</code> | removes the directory delimiter from <i>dir</i> if <i>dir</i> ends with it. |
| <i>list<string></i> | <code>get_directories(<i>string dir</i>)</code> | returns the list of names of all sub-directories in directory <i>dir</i> . |
| <i>list<string></i> | <code>get_files(<i>string dir</i>)</code> | returns the list of names of all regular files in directory <i>dir</i> . |
| <i>list<string></i> | <code>get_files(<i>string dir, string pattern</i>)</code> | returns the list of names of all regular files in directory <i>dir</i> matching pattern. |
| <i>list<string></i> | <code>get_entries(<i>string dir</i>)</code> | returns the list of all entries (directory and files) of directory <i>dir</i> . |
| <i>bool</i> | <code>create_directory(<i>string fname</i>)</code> | creates a directory with name <i>dname</i> , returns <i>true</i> on success. |
| <i>bool</i> | <code>is_directory(<i>string fname</i>)</code> | returns true if <i>fname</i> is the path name of a directory and false otherwise. |
| <i>bool</i> | <code>is_file(<i>string fname</i>)</code> | returns true if <i>fname</i> is the path name of a regular file and false otherwise. |
| <i>bool</i> | <code>is_link(<i>string fname</i>)</code> | returns true if <i>fname</i> is the path name of a symbolic link and false otherwise. |

<i>size_t</i>	<code>size_of_file(<i>string fname</i>)</code>	returns the size of file <i>fname</i> in bytes.
<i>time_t</i>	<code>time_of_file(<i>string fname</i>)</code>	returns the time of last access to file <i>fname</i> .
<i>string</i>	<code>tmp_dir_name()</code>	returns name of the directory for temporary files.
<i>string</i>	<code>tmp_file_name()</code>	returns a unique name for a temporary file.
<i>bool</i>	<code>delete_file(<i>string fname</i>)</code>	deletes file <i>fname</i> returns true on success and false otherwise.
<i>bool</i>	<code>copy_file(<i>string src, string dest</i>)</code>	copies file <i>src</i> to file <i>dest</i> returns true on success and false otherwise.
<i>bool</i>	<code>move_file(<i>string src, string dest</i>)</code>	moves file <i>src</i> to file <i>dest</i> returns true on success and false otherwise.
<i>bool</i>	<code>chmod_file(<i>string fname, string option</i>)</code>	change file permission bits.
<i>bool</i>	<code>open_file(<i>string fname, string suffix</i>)</code>	opens file <i>fname</i> with application associated to suffix.
<i>bool</i>	<code>open_file(<i>string fname</i>)</code>	opens file <i>fname</i> with associated application.
<i>int</i>	<code>compare_files(<i>string fname1, string fname2</i>)</code>	returns 1 if the contents of <i>fname1</i> and <i>fname2</i> differ and 0 otherwise.
<i>string</i>	<code>first_file_in_path(<i>string fname, string path, char sep = ':'</i>)</code>	searches all directories in string <i>path</i> (separated by <i>sep</i>) for the first directory <i>dir</i> that contains a file with name <i>fname</i> and returns <i>dir/fname</i> (the empty string if no such directory is contained in path).
<i>list<string></i>	<code>get_disk_drives()</code>	returns the list of all disk drives of the system.

4.13 Sockets (`leda_socket`)

1. Definition

A data **packet** consists of a sequence of bytes (in `C` of type `unsigned char`) $c_0, c_1, c_2, c_3, x_1, \dots, x_n$. The first four bytes encode the number n of the following bytes such that $n = c_0 + c_1 \cdot 2^8 + c_2 \cdot 2^{16} + c_3 \cdot 2^{24}$. The LEDA data type `leda_socket` offers, in addition to the operations for establishing a socket connection, functions for sending and receiving packets across such a connection. It is also possible to set a receive limit; if such a receive limit is set, messages longer than the limit will be refused. If the limit is negative (default), no messages will be refused.

In particular, the following operations are available:

```
#include < LEDA/system/socket.h >
```

2. Creation

```
leda_socket S(const char * host, int port);
```

creates an instance S of type `leda_socket` associated with host name $host$ and port number $port$.

```
leda_socket S(const char * host);
```

creates an instance S of type `leda_socket` associated with host name $host$.

```
leda_socket S;            creates an instance  $S$  of type leda_socket.
```

3. Operations

```
void S.set_host(const char * host)
```

sets the host name to $host$.

```
void S.set_port(int port)    sets the port number to  $port$ .
```

```
size_t S.get_limit()        returns the receive limit parameter.
```

```
void S.set_limit(size_t limit)
```

sets the receive limit parameter to $limit$. If a negative limit is set, the limit parameter will be ignored.

```
void S.set_qlength(int len) sets the queue length to  $len$ .
```

```
void S.set_timeout(int sec)
```

sets the timeout interval to sec seconds.

```
void S.set_error_handler(void (*f)(leda_socket& , string))
```

sets the error handler to function f .

<i>void</i>	<i>S.set_receive_handler(void (*f)(leda_socket& , size_t, size_t))</i>	sets the receive handler to function <i>f</i> .
<i>void</i>	<i>S.set_send_handler(void (*f)(leda_socket& , size_t, size_t))</i>	sets the send handler to function <i>f</i> .
<i>string</i>	<i>S.get_host()</i>	returns the host name.
<i>int</i>	<i>S.get_port()</i>	returns the port number.
<i>int</i>	<i>S.get_timeout()</i>	returns the timeout interval length in seconds.
<i>int</i>	<i>S.get_qlength()</i>	returns the queue length.
<i>string</i>	<i>S.get_ip()</i>	returns the ip address.
<i>bool</i>	<i>S.connect(int sec = 10)</i>	tries to establish a connection from a client to a server. If the connection can be established within <i>sec</i> seconds, the operation returns <i>true</i> and <i>false</i> otherwise.
<i>bool</i>	<i>S.listen()</i>	creates a socket endpoint on the server, performs address binding and signals readiness of a server to receive data.
<i>bool</i>	<i>S.accept()</i>	the server takes a request from the queue.
<i>void</i>	<i>S.disconnect()</i>	ends a connection.

Sending and receiving packets

<i>void</i>	<i>S.send_file(string fname)</i>	sends the contents of file <i>fname</i> .
<i>void</i>	<i>S.send_file(string fname, int buf_sz)</i>	sends <i>fname</i> using a buffer of size <i>buf_sz</i> .
<i>void</i>	<i>S.send_bytes(char * buf, size_t num)</i>	sends <i>num</i> bytes starting at address <i>buf</i> .
<i>void</i>	<i>S.send_string(string msg)</i>	sends string <i>msg</i> .
<i>void</i>	<i>S.send_int(int x)</i>	sends (a text representation of) integer <i>x</i> .
<i>bool</i>	<i>S.receive_file(string fname)</i>	receives data and writes it to file <i>fname</i> .

<i>char*</i>	<i>S.receive_bytes(size_t& num)</i>	receives <i>num</i> bytes. The function allocates memory and returns the first address of the allocated memory. <i>num</i> is used as the return parameter for the number of received bytes.
<i>int</i>	<i>S.receive_bytes(char * buf, size_t buf_sz)</i>	receives at most <i>buf_sz</i> bytes and writes them into the buffer <i>buf</i> . It returns the number of bytes supplied by the sender (maybe more than <i>buf_sz</i>), or -1 in case of an error.
<i>bool</i>	<i>S.receive_string(string& s)</i>	receives string <i>s</i> .
<i>bool</i>	<i>S.receive_int(int& x)</i>	receives (a text representation of) an integer and stores its value in <i>x</i> .
<i>bool</i>	<i>S.wait(string s)</i>	returns <i>true</i> , if <i>s</i> is received, <i>false</i> otherwise.

The following template functions can be used to send/receive objects supporting input and output operators for iostreams.

```
template <class T>
void      socket_send_object(const T& obj, leda_socket& sock)
                sends obj to the connection partner of sock.
```

```
template <class T>
void      socket_receive_object(T& obj, leda_socket& sock)
                receives obj from the connection partner of sock.
```

4.14 Socket Streambuffer (`socket_streambuf`)

1. Definition

An instance *sb* of class *socket_streambuf* can be used as an adapter: It turns a *leda_socket* *s* into a C++-streambuf object. This object can be used in standard C++ *ostreams* and *istreams* to make the communication through the socket easier. A *socket_streambuf* can also be applied within an *encoding_ostream* or a *decoding_istream* provided by LEDA to send compressed or encrypted data over a socket connection (see Sections 10.19 and 10.20). Observe that *socket_streambuf* itself does not apply cryptography to secure the transmitted data. All data is sent as it is. If you want to secure your data, consider using the class *secure_socket_streambuf* (see Section 11.7).

If two parties want to use the class *socket_streambuf* to exchange data they have to do the following. First they establish a connection through *leda_sockets*. Then each party constructs an instance of the class *socket_streambuf* which is attached to its socket. This is shown in an example at the end of this manual page.

Every instance *sb* has an out-buffer where outgoing data is buffered before it is sent through the socket over the internet. In addition it has an in-buffer to store data that has been received through the socket. The user may specify the maximum size of each buffer. The actual size of each buffer is determined in a negotiation between the server and the client at the beginning of the communication. The size of outgoing packets from the server is set to the minimum of the out-buffer size of the server and the in-buffer size of the client. The size of the incoming packets is determined in an analogous way.

```
#include < LEDA/coding/socket_streambuf.h >
```

2. Creation

```
socket_streambuf sb(leda_socket& s, wint32 out_buf_sz = DefaultBufferSize,
                   wint32 in_buf_sz = DefaultBufferSize,
                   bool send_acknowledge = false);
```

creates a *sb* and attaches it to the socket *s*. The parameters *out_buf_sz* and *in_buf_sz* determine the maximum size of the out-buffer and the in-buffer. *send_acknowledge* specifies whether an acknowledgement is sent for every received packet.

Precondition: The connection between the server and the client must have been established when *sb* is created.

3. Operations

The class *socket_streambuf* inherits most of its operations from the class *streambuf* that belongs to the C++ standard library. Usually there is no need to call these operations explicitly. (You can find documentation for *streambuf* at <http://www.cplusplus.com>)

<i>bool</i>	<i>sb.failed()</i>	returns whether a failure has occurred.
<i>string</i>	<i>sb.get_error()</i>	returns an error message (if available).
<i>void</i>	<i>sb.sputEOF()</i>	signals the end of the transmission to the receiving socket, so that it does not wait for further data. (This function is called automatically in the destructor unless it has been called explicitly by the user. If <i>sb</i> is not immediately destroyed after the end of the transmission then you should call <i>sputEOF</i> explicitly, otherwise the receiving party might incur a timeout error.)
<i>bool</i>	<i>sb.has_put_EOF()</i>	returns whether EOF has already been sent.
<i>bool</i>	<i>sb.has_got_EOF()</i>	returns whether EOF has already been received.
<i>leda_socket&</i>	<i>sb.get_socket()</i>	returns the socket to which <i>sb</i> is attached.
<i>uint32</i>	<i>sb.get_outgoing_packet_size()</i>	returns the (actual) outgoing packet size.
<i>uint32</i>	<i>sb.get_incoming_packet_size()</i>	returns the (actual) incoming packet size.
<i>bool</i>	<i>sb.waits_for_acknowledge()</i>	returns whether <i>sb</i> expects an acknowledgement for outgoing packets.
<i>bool</i>	<i>sb.sends_acknowledge()</i>	returns whether <i>sb</i> sends an acknowledgement for incoming packets.

4. Example

The following example shows how the usage of *sb* from the server and from the client side. In our example the server sends a string, which is received by the client. (Note that it would also be possible that the client sends and the server receives data.)

In order to add compression to the example simply replace “*ostream*” by “*encoding_ostream<Coder>*” and “*istream*” by “*decoding_istream*” as indicated in the comments.

```
void socket_example_server(int port)
{
    leda_socket sock;
    sock.set_port(port);

    // open port
```

```
if (! sock.listen()) {
    cerr << sock.get_error() << endl; return;
}
for (;;) {
    // establish connection
    if (! sock.accept()) {
        cerr << sock.get_error() << endl; continue;
    }

    // send data
    {
        socket_streambuf sb(sock);
        ostream out(&sb);
        // or: encoding_ostream<PPMIICoder> out(&sb);
        out << "Hello world!" << endl;
    } // destroys sb and calls sb.sputEOF() automatically
}

void socket_example_client(int port, string host)
{
    leda_socket sock;
    sock.set_host(host);
    sock.set_port(port);

    // establish connection
    if (! sock.connect()) {
        cerr << sock.get_error() << endl; return;
    }

    // receive data
    socket_streambuf sb(sock);
    istream in(&sb);
    // or: decoding_istream<PPMIICoder> in(&sb);
    string str;
    str.read_line(in);
    cout << "received: " << str << endl;
}
```

4.15 Some Useful Functions (misc)

The following functions and macros are defined in <LEDA/core/misc.h>.

<i>int</i>	<code>readInt(<i>string s</i>)</code>	prints <i>s</i> and reads an integer from <i>cin</i> .
<i>double</i>	<code>readReal(<i>string s</i>)</code>	prints <i>s</i> and reads a real number from <i>cin</i> .
<i>string</i>	<code>readString(<i>string s</i>)</code>	prints <i>s</i> and reads a line from <i>cin</i> .
<i>char</i>	<code>readChar(<i>string s</i>)</code>	prints <i>s</i> and reads a character from <i>cin</i> .
<i>int</i>	<code>Yes(<i>string s</i>)</code>	returns <code>(readChar(s) == 'y')</code> .
<i>bool</i>	<code>getEnvironment(<i>string var</i>)</code>	returns <i>true</i> if variable <i>var</i> is defined in the current environment and <i>false</i> otherwise.
<i>bool</i>	<code>getEnvironment(<i>string var, string& val</i>)</code>	if variable <i>var</i> is defined in the current environment its value is assigned to <i>val</i> and the result is <i>true</i> . Otherwise, the result is <i>false</i> .
<i>float</i>	<code>usedTime()</code>	returns the currently used cpu time in seconds. (The class <i>timer</i> in Section 4.16 provides a nicer interface for time measurements.)
<i>float</i>	<code>usedTime(<i>float& T</i>)</code>	returns the cpu time used by the program from time <i>T</i> up to this moment and assigns the current time to <i>T</i> .
<i>float</i>	<code>elapsedTime()</code>	returns the current daytime time in seconds.
<i>float</i>	<code>elapsedTime(<i>float& T</i>)</code>	returns the elapsed time since time <i>T</i> and assigns the current elapsed time to <i>T</i> .
<i>float</i>	<code>realTime()</code>	same as <i>elapsedTime()</i> .
<i>float</i>	<code>realTime(<i>float& T</i>)</code>	same as <i>elapsedTime(T)</i> .
<i>void</i>	<code>printStatistics()</code>	prints a summary of the currently used memory, which is used by LEDA's internal memory manager. This only reports on memory usage of LEDA's internal types and user-defined types that implement the LEDA_MEMORY macro (see Section 4.9).
<i>bool</i>	<code>isSpace(<i>char c</i>)</code>	returns <i>true</i> if <i>c</i> is a white space character.

void `sleep(double sec)` suspends execution for *sec* seconds.

void `wait(double sec)` suspends execution for *sec* seconds.

double `truncate(double x, int k = 10)`
returns a double whose mantissa is truncated after $k - 1$ bits after the binary point, i.e, if $x \neq 0$ then the binary representation of the mantissa of the result has the form d.dddddddd, where the number of d's is equal to k . There is a corresponding function for *integers*; it has no effect.

`template <class T>`
`const T& min(const T& a, const T& b)`
returns the minimum of *a* and *b*.

`template <class T>`
`const T& max(const T& a, const T& b)`
returns the maximum of *a* and *b*.

`template <class T>`
`void swap(T& a, T& b)` swaps values of *a* and *b*.

4.16 Timer (timer)

1. Definition

The class *timer* facilitates time measurements. An instance *t* has two states: *running* or *stopped*. It measures the time which elapses while it is in the state *running*. The state depends on a (non-negative) internal counter, which is incremented by every *start* operation and decremented by every *stop* operation. The timer is *running* iff the counter is not zero. The use of a counter (instead of a boolean flag) to determine the state is helpful when a recursive function *f* is measured, which is shown in the example below:

```
#include <LEDA/system/timer.h>
leda::timer f_timer;

void f()
{
    f_timer.start();

    // do something ...
    f(); // recursive call
    // do something else ...

    f_timer.stop(); // timer is stopped when top-level call returns
}

int main()
{
    f();
    std::cout << "time spent in f " << f_timer << "\n"; return 0;
}
```

Let us analyze this example. When *f* is called in *main*, the timer is in the state *stopped*. The first *start* operation (in the top-level call) increments the counter from zero to one and puts the timer into the state *running*. In a recursive call the counter is incremented at the beginning and decremented upon termination, but the timer remains in the state *running*. Only when the top-level call of *f* terminates and returns to *main*, the counter is decremented from one to zero, which puts the timer into the state *stopped*. So the timer measures the total running time of *f* (including recursive calls).

```
#include <LEDA/system/timer.h >
```

2. Types

timer::measure auxiliary class to facilitate measurements (see example below).

3. Creation

`timer t(const string& name, bool report_on_destruction = true);`

creates an instance `t` with the given `name`. If `report_on_destruction` is true, then the timer reports upon its destruction how long it has been running in total. The initial state of the timer is *stopped*.

`timer t;`

creates an unnamed instance `t` and sets the `report_on_destruction` flag to false. The initial state of the timer is *stopped*.

4. Operations

`void t.reset();` sets the internal counter and the total elapsed time to zero.

`void t.start();` increments the internal counter.

`void t.stop();` decrements the internal counter. (If the counter is already zero, nothing happens.)

`void t.restart();` short-hand for `t.reset() + t.start()`.

`void t.halt();` sets the counter to zero, which forces the timer into the state *stopped* no matter how many *start* operations have been executed before.

`bool t.is_running();` returns if `t` is currently in the state *running*.

`float t.elapsed_time();` returns how long (in seconds) `t` has been in the state *running* (since the last *reset*).

`void t.set_name(const string& name)`
sets the name of `t`.

`string t.get_name();` returns the name of `t`.

`void t.report_on_destruction(bool do_report = true)`
sets the flag `report_on_destruction` to `do_report`.

`bool t.will_report_on_destruction();`
returns whether `t` will issue a report upon its destruction.

5. Example

We give an example demonstrating the use of the class `measure`. Note that the function below has several `return` statements, so it would be tedious to stop the timer “by hand”.

```
#include <LEDA/system/timer.h>
```

```
unsigned fibonacci(unsigned n)
{
    static leda::timer t("fibonacci");
        // report total time upon destruction of t

    leda::timer::measure m(t);
        // starts the timer t when m is constructed, and stops t
        // when m is destroyed, i.e. when the function returns

    if (n < 1) return 0;
    else if (n == 1) return 1;
    else return fibonacci(n-1) + fibonacci(n-2);
}

int main()
{
    std::cout << fibonacci(40) << "\n";
    return 0; // reports "Timer(fibonacci): X.XX s" upon termination
}
```

4.17 Counter (counter)

1. Definition

The class *counter* can be used during profiling to count how often certain code is executed. An example is given below.

```
#include <LEDA/system/counter.h >
```

2. Creation

```
counter c(const string& name, bool report_on_destruction = true);
```

creates an instance *c* with the given *name*. If *report_on_destruction* is true, then the counter reports its value upon destruction. The initial value of the counter is zero.

```
counter c;
```

creates an unnamed instance *c* and sets the *report_on_destruction* flag to false. The initial value of the counter is zero.

3. Operations

```
void c.reset()
```

sets the value of *c* to zero.

```
void c.set_value(const unsigned long val)
```

sets the value of *c* to *val*.

```
const unsigned long c.get_value()
```

returns the current value of *c*.

```
const unsigned long c.increment()
```

increments *c* and returns its new value. (We also provide the operator ++.)

```
void c.set_name(const string& name)
```

sets the name of *c*.

```
string c.get_name()
```

returns the name of *c*.

```
void c.report_on_destruction(bool do_report = true)
```

sets the flag *report_on_destruction* to *do_report*.

```
bool c.will_report_on_destruction()
```

returns whether *c* will issue a report upon its destruction.

4. Example

In the example below we count how often the function *fibonacci* is executed.

```
#include <LEDA/system/counter.h>
```

```
unsigned fibonacci(unsigned n)
{
    static leda::counter cnt("fibonacci");
    // report upon destruction of cnt
    ++cnt;

    if (n < 1) return 0;
    else if (n == 1) return 1;
    else return fibonacci(n-1) + fibonacci(n-2);
}

int main()
{
    std::cout << fibonacci(40) << "\n";
    return 0; // reports "Counter(fibonacci) = 331160281" upon termination
}
```

4.18 Two Tuples (two_tuple)

1. Definition

An instance p of type $two_tuple<A, B>$ is a two-tuple (a, b) of variables of types A , and B , respectively.

Related types are two_tuple , $three_tuple$, and $four_tuple$.

```
#include < LEDA/core/tuple.h >
```

2. Types

$two_tuple<A, B>::first_type$ the type of the first component.

$two_tuple<A, B>::second_type$
the type of the second component.

3. Creation

$two_tuple<A, B> p;$ creates an instance p of type $two_tuple<A, B>$. All components are initialized to their default value.

$two_tuple<A, B> p(const A\& u, const B\& v);$
creates an instance p of type $two_tuple<A, B>$ and initializes it with the value (u, v) .

4. Operations

$A\& p.first()$ returns the A -component of p . If p is a const-object the return type is A .

$B\& p.second()$ returns the B -component of p . If p is a const-object the return type is B .

template <class A , class B >
 $bool const two_tuple<A, B>\& p == const two_tuple<A, B>\& q$
equality test for two_tuples . Each of the component types must have an equality operator.

template <class A , class B >
 $int compare(const two_tuple<A, B>\& p, const two_tuple<A, B>\& q)$
lexicographic ordering for two_tuples . Each of the component types must have a compare function.

template <class A , class B >

int Hash(*const two_tuple*<*A, B*>& *p*)

hash function for *two_tuples*. Each of the component types must have a Hash function.

5. Implementation

The obvious implementation is used.

4.19 Three Tuples (*three_tuple*)

1. Definition

An instance *p* of type *three_tuple*<*A, B, C*> is a three-tuple (*a, b, c*) of variables of types *A, B, and C*, respectively.

Related types are *two_tuple*, *three_tuple*, and *four_tuple*.

```
#include < LEDA/core/tuple.h >
```

2. Types

three_tuple<*A, B, C*>::*first_type*

the type of the first component.

three_tuple<*A, B, C*>::*second_type*

the type of the second component.

three_tuple<*A, B, C*>::*third_type*

the type of the third component.

3. Creation

three_tuple<*A, B, C*> *p*; creates an instance *p* of type *three_tuple*<*A, B, C*>. All components are initialized to their default value.

three_tuple<*A, B, C*> *p*(*const A*& *u, const B*& *v, const C*& *w*);

creates an instance *p* of type *three_tuple*<*A, B, C*> and initializes it with the value (*u, v, w*).

4. Operations

A& *p*.first() returns the *A*-component of *p*. If *p* is a const-object the return type is *A*.

B& *p*.second() returns the *B*-component of *p*. If *p* is a const-object the return type is *B*.

C& *p*.third() returns the *C*-component of *p*. If *p* is a const-object the return type is *C*.

template <*class A, class B, class C*>

bool *const three_tuple*<*A, B, C*>& *p* == *const three_tuple*<*A, B, C*>& *q*

equality test for *three_tuples*. Each of the component types must have an equality operator.

template <*class A, class B, class C*>

int *compare*(*const three_tuple*<*A, B, C*>& *p, const three_tuple*<*A, B, C*>& *q*)

lexicographic ordering for *three_tuples*. Each of the component types must have a compare function.

template <*class A, class B, class C*>

int *Hash*(*const three_tuple*<*A, B, C*>& *p*)

hash function for *three_tuples*. Each of the component types must have a Hash function.

5. Implementation

The obvious implementation is used.

4.20 Four Tuples (*four_tuple*)

1. Definition

An instance *p* of type *four_tuple*<*A, B, C, D*> is a four-tuple (*a, b, c, d*) of variables of types *A, B, C, and D*, respectively.

Related types are *two_tuple*, *three_tuple*, and *four_tuple*.

```
#include < LEDA/core/tuple.h >
```

2. Types

four_tuple<*A, B, C, D*>::*first_type*

the type of the first component.

four_tuple<*A, B, C, D*>::*second_type*

the type of the second component.

four_tuple<*A, B, C, D*>::*third_type*

the type of the third component.

four_tuple<*A, B, C, D*>::*fourth_type*

the type of the fourth component.

3. Creation

four_tuple<*A*, *B*, *C*, *D*> *p*; creates an instance *p* of type *four_tuple*<*A*, *B*, *C*, *D*>. All components are initialized to their default value.

four_tuple<*A*, *B*, *C*, *D*> *p*(*const A*& *u*, *const B*& *v*, *const C*& *w*, *const D*& *x*);
creates an instance *p* of type *four_tuple*<*A*, *B*, *C*, *D*> and initializes it with the value (*u*, *v*, *w*, *x*).

4. Operations

A& *p*.first() returns the *A*-component of *p*. If *p* is a const-object the return type is *A*.

B& *p*.second() returns the *B*-component of *p*. If *p* is a const-object the return type is *B*.

C& *p*.third() returns the *C*-component of *p*. If *p* is a const-object the return type is *C*.

D& *p*.fourth() returns the *D*-component of *p*. If *p* is a const-object the return type is *D*.

template <*class A*, *class B*, *class C*, *class D*>

bool *const four_tuple*<*A*, *B*, *C*, *D*>& *p* == *const four_tuple*<*A*, *B*, *C*, *D*>& *q*
equality test for *four_tuples*. Each of the component types must have an equality operator.

template <*class A*, *class B*, *class C*, *class D*>

int *compare*(*const four_tuple*<*A*, *B*, *C*, *D*>& *p*, *const four_tuple*<*A*, *B*, *C*, *D*>& *q*)
lexicographic ordering for *four_tuples*. Each of the component types must have a compare function.

template <*class A*, *class B*, *class C*, *class D*>

int *Hash*(*const four_tuple*<*A*, *B*, *C*, *D*>& *p*)
hash function for *four_tuples*. Each of the component types must have a Hash function.

5. Implementation

The obvious implementation is used.

6. Example

We customize *four_tuples* and define a *h_array* for them.

```
#define prio() first()
#define inf() second()
```

```
#define pq_item() third()
#define part_item() fourth()
typedef four_tuple<int,int,int,int> my_qu;

my_qu q;
my_qu q1(2,2,0,0);
q.prio() = 5;

h_array<my_qu,int> M;
M[my_qu(2,2,nil,nil)] = 5;
```

4.21 A date interface (`date`)

1. Definition

An instance of the data type *date* represents a date consisting of a day *d*, a month *m* and year *y*. It will be denoted by *d.m.y*. Valid dates range from 1.1.1 to 31.12.9999. A date is *valid* if it lies in the range and is correct according to the gregorian calendar, i.e. a year *y* is considered to be a leap year iff *y* is divisible by 4 but not by 100 or *y* is divisible by 400. The year part *y* is always a four digit number, so that each date in the valid range has an unambiguous representation.

With the *date* class there is associated an input and an output format, each is described by a string which determines how instances of type *date* are read from streams and how they are printed to streams. Printing the date 4.11.1973 using the format string "dd.mm.yy" will result in "04.11.73", whereas printing the same date using "mm/dd/yyyy" will produce "11/04/1973". The *date* type provides some predefined formats, it also allows user-defined formats and supports different languages (for month names and weekday names). A format string consists of tokens, not all tokens are valid for both input and output formats. But any sequence of valid tokens forms a valid format string, the only exception to this rule is the *delim* token (see the table below). In order to avoid ambiguities when parsing a format string the longest prefix rule is applied, which ensures that *dd* is parsed as a single token and not as twice the token *d*.

An input format does not have to refer to all the three parts (day, month and year) of a date; the parts which do not appear in the format are left unchanged when the format is used in an update operation. Applying the format "d.m.", for example, changes the day and the month part but not the year part. (The result of using input formats referring twice to the same part as in "m M" is undefined.) Please see table 4.1 for an overview of all possible tokens.

```
#include <LEDA/system/date.h >
```

2. Types

```
date::month { Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec }
```

The enumeration above allows to specify months by their name. Of course, one can also specify months by their number writing `date::month(m)`.

```
date::language { user_deflang, local, english, german, french }
```

When the language is set to *local*, the month names and weekday names are read from the local environment; the other identifiers are self-explanatory.

Table 4.1: Token Overview

token	input	output	description
d	yes	yes	day with 1 or 2 digits
dd	yes	yes	day with 2 digits (possibly with leading zero)
dth	yes	yes	day as abbreviated english ordinal number (1st, 2nd, 3rd, 4th, ...)
m	yes	yes	month with 1 or 2 digits
mm	yes	yes	month with 2 digits (possibly with leading zero)
M	yes	yes	month name (when used in an input format this token must be followed by a single char <i>c</i> which does not belong to any month name, <i>c</i> is used to determine the end of the name. e.g.: "d.M.yy")
M:l	yes	yes	the first <i>l</i> characters of the month name (<i>l</i> must be a single digit)
yy	yes	yes	year with 2 digits (yy is considered to represent a year in [1950;2049])
yyyy	yes	yes	year with 4 digits
[yy]yy	yes	yes	input: year with 2 or 4 digits / output: same as yyyy
w	no	yes	calendar week (in the range [1;53]) (see <i>get_week()</i> for details)
diy	no	yes	day in the year (in the range [1,366])
dow	no	yes	day of the week (1=Monday, ..., 7=Sunday)
DOW	no	yes	name of the weekday
DOW:l	no	yes	the first <i>l</i> characters of the weekday name (<i>l</i> must be a single digit)
"txt"	yes	yes	matches/prints <i>txt</i> (<i>txt</i> must not contain a double quote)
'txt'	yes	yes	matches/prints <i>txt</i> (<i>txt</i> must not contain a single quote)
<i>c</i>	yes	yes	matches/prints <i>c</i> ($c \notin \{d, m, M, ?, *, ;\}$)
?	yes	no	matches a single arbitrary character
* <i>c</i>	yes	no	matches any sequence of characters ending with <i>c</i>
;	yes	yes	separates different formats, e.g. "d.M.yy;dd.mm.yy" input: the first format that matches the input is used output: all but the first format is ignored
delim: <i>c</i>	yes	no	<i>c</i> serves as delimiter when reading input from streams (If this token is used, it must be the first in the format string.) When you use "delim:\n;d.M.yy\n;d.m.yyyy\n" as input format to read a date from a stream, everything until the first occurrence of "\n" is read and then the format "d.M.yy\n;d.m.yyyy\n" is applied.

date::format { user_def_fmt, US_standard, german_standard, colons, hyphens }

The format *US_standard* is an abbreviation for *mm/dd/[yy]yy*, the format *german_standard* is the same as *dd.mm.[yy]yy*, the other formats are the same as the latter except that the periods are replaced by colons/hyphens.

3. Creation

date *D*; creates an instance *D* of type *date* and initializes it to the current date.

date *D*(*int* *d*, *month* *m*, *int* *y*);
creates an instance *D* of type *date* and initializes it to *d.m.y*.
Precondition: *d.m.y* represents a valid date.

date *D*(*string* *date_str*, *bool* *swallow* = *true*);
creates an instance *D* of type *date* and initializes it to date given in *date_str*.
If *swallow* is *true*, then the format "*m/d/[yy]yy;d?m?[yy]yy*" is used to parse *date_str*, otherwise the current input format is applied.
Precondition: *date_str* represents a valid date.

4. Operations

4.1 Languages and Input/Output Formats

void *date::set_language*(*language* *l*)
sets the language to *l*, which means that the month names and the weekday names are set according to the language.
Precondition: *l* ≠ *user_def_lang*

void *date::set_month_names*(*const char* * *names*[])
sets the names for the months and changes the language to *user_def_lang*.
Precondition: *names*[0..11] contains the names for the months from January to December.

void *date::set_dow_names*(*const char* * *names*[])
sets the names for the weekdays and changes the language to *user_def_lang*.
Precondition: *names*[0..6] contains the names for the weekdays from Monday to Sunday.

language *date::get_language*() returns the current language.

void *date::set_input_format*(*format* *f*)
sets the input format to *f*.
Precondition: *f* ≠ *user_def_fmt*

void *date::set_input_format*(*string* *f*)
sets the input format to the user-defined format in *f*.
Precondition: *f* is a valid format string

<i>format</i>	<code>date::get_input_format()</code>	returns the current input format.
<i>string</i>	<code>date::get_input_format_str()</code>	returns the current input format string.
<i>void</i>	<code>date::set_output_format(format f)</code>	sets the output format to <i>f</i> . <i>Precondition: f ≠ user_def_fmt</i>
<i>void</i>	<code>date::set_output_format(string f)</code>	sets the output format to the user-defined format in <i>f</i> . <i>Precondition: f is a valid format string</i>
<i>format</i>	<code>date::get_output_format()</code>	returns the current output format.
<i>string</i>	<code>date::get_output_format_str()</code>	returns the current output format string.

4.2 Access and Update Operations

All update operations which may fail have in common that the date is changed and *true* is returned if the new date is valid, otherwise *false* is returned and the date is left unchanged. (Note that the functions *add_to_day*, *add_to_month* and *add_to_year* can only fail if the valid range (1.1.1 – 31.12.9999) is exceeded.)

<i>void</i>	<code>D.set_to_current_date()</code>	sets <i>D</i> to the current date.
<i>bool</i>	<code>D.set_date(int d, month m, int y)</code>	<i>D</i> is set to <i>d.m.y</i> (if <i>d.m.y</i> is valid).
<i>bool</i>	<code>D.set_date(const string date_str, bool swallow = true)</code>	<i>D</i> is set to the date contained in <i>date_str</i> . If <i>swallow</i> is <i>true</i> , then the format " <i>m/d/[yy]yy; d?m?[yy]yy</i> " is used to parse <i>date_str</i> , otherwise the current input format is applied.
<i>string</i>	<code>D.get_date()</code>	returns a string representation of <i>D</i> in the current output format.
<i>int</i>	<code>D.get_day()</code>	returns the day part of <i>D</i> , i.e. if <i>D</i> is <i>d.m.y</i> then <i>d</i> is returned.
<i>month</i>	<code>D.get_month()</code>	returns the month part of <i>D</i> .

<i>string</i>	<code>D.get_month_name()</code>	returns the name of the month of D in the current language.
<i>int</i>	<code>D.get_year()</code>	returns the year part of D .
<i>bool</i>	<code>D.set_day(int d)</code>	sets the day part of D to d , i.e. if D is $d'.m.y$ then D is set to $d.m.y$.
<i>bool</i>	<code>D.add_to_day(int d)</code>	adds d days to D (cf. arithmetic operations).
<i>bool</i>	<code>D.set_month(month m)</code>	sets the month part of D to m .
<i>bool</i>	<code>D.add_to_month(int m)</code>	adds m months to the month part of D . Let D be $d.m'.y$, then it is set to $d.(m' + m).y$. If this produces an overflow (i.e. $m' + m > 12$) then the month part is repeatedly decremented by 12 and the year part is simultaneously incremented by 1, until the month part is valid. (An underflow (i.e. $m' + m < 1$) is treated analogously.) The day part of the result is set to the minimum of d and the number of days in the resulting month.
<i>bool</i>	<code>D.set_year(int y)</code>	sets the year part of D to y .
<i>bool</i>	<code>D.add_to_year(int y)</code>	adds y years to the year part of D . (If D has the form $29.2.y'$ and $y' + y$ is no leap year, then D is set to $28.2.(y' + y)$.)
<i>int</i>	<code>D.get_day_of_week()</code>	returns the day of the week of D . (1=Monday, 2=Tuesday, ..., 7=Sunday)
<i>string</i>	<code>D.get_dow_name()</code>	returns the name of the weekday of D in the current language.
<i>int</i>	<code>D.get_week()</code>	returns the number of the calendar week of D (range [1,53]). A week always ends with a Sunday. Every week belongs to the year which covers most of its days. (If the first Sunday of a year occurs before the fourth day of the year, then all days up to this Sunday belong to the last week of the preceding year. Similarly, if there are less than 4 days left after the last Sunday of a year, then these days belong to the first week of the succeeding year.)
<i>int</i>	<code>D.get_day_in_year()</code>	returns the number of the day in the year of D (range [1;366]).

4.3 Arithmetic Operations

date $D + \text{int } d$ returns the date d days after D .

date $D - \text{int } d$ returns the date d days before D .

The related operators $++$, $--$, $+=$, $-=$ and all comparison operators are also provided.

int $D - \text{const date\& } D2$ returns the difference between D and $D2$ in days.

int $D.\text{days_until}(\text{const date\& } D2)$
returns $D2 - D$.

int $D.\text{months_until}(\text{const date\& } D2)$
if $D2 \geq D$ then $\max\{m : D.\text{add_to_month}(m) \leq D2\}$ is returned; otherwise the result is $-D2.\text{months_until}(D)$.

int $D.\text{years_until}(\text{const date\& } D2)$
if $D2 \geq D$ then $\max\{y : D.\text{add_to_year}(y) \leq D2\}$ is returned; otherwise the result is $-D2.\text{years_until}(D)$.

4.4 Miscellaneous Predicates

bool $\text{date}::\text{is_valid}(\text{int } d, \text{month } m, \text{int } y)$
returns *true* iff $d.m.y$ represents a valid date.

bool $\text{date}::\text{is_valid}(\text{string } d, \text{bool } \text{swallow} = \text{true})$
returns *true* iff d represents a valid date. If *swallow* is *true* the swallow format (cf. *set_date*) is used, otherwise the current input format is tried.

bool $\text{date}::\text{is_leap_year}(\text{int } y)$
returns *true* iff y is a leap year.

bool $D.\text{is_last_day_in_month}()$
let D be $d.m.y$; the function return *true* iff d is the last day in the month m of the year y .

5. Example

We count the number of Sundays in the days from now to 1.1.2020 using the following code chunk:

```
int number_of_Sundays = 0;
for (date D; D<=date(1,date::Jan,2020); ++D)
    if (D.get_day_of_week() == 7) ++number_of_Sundays;
```

Now we show an example in which different output formats are used:

```
date D(2,date::month(11),1973);
date::set_output_format(date::german_standard);
cout << D << endl; // prints "02.11.1973"
date::set_language(date::english);
date::set_output_format("dth M yyyy");
cout << D << endl; // prints "2nd November 1973"
```

Finally, we give an example for the usage of a multi-format. One can choose among 3 different formats:

1. If one enters only day and month, then the year part is set to the current year.
2. If one enters day, month and year providing only 2 digits for the year, the year is considered to be in the range [1950, 2049]. (Note that the date 1.1.10 must be written as "1.1.0010".)
3. One may also specify the date in full detail by entering 4 digits for the year.

The code to read the date in one of the formats described above looks like this:

```
D.set_to_current_date(); // set year part to current year
date::set_input_format("delim:\n;d.m.\n;d.m.[yy]yy\n");
cin >> D; cout << D << endl;
```

Chapter 5

Alignment Data Types

This section describes several data types being used in the area of bioinformatics. The data types *alphabet* and *score_matrix* are just ingredients needed for the *alignment* type. *distance*, *string_matching*, and *alignment* are classes providing comparison and alignment functionality for a pair of strings. This chapter should be considered as the beginning of a new module. Users are encouraged to send there expectations with respect to future functionality to support@algorithmic-solutions.com.

5.1 Alphabet (`alphabet`)

1. Definition

An instance *A* of the data type *alphabet* is an object containing a collection of letters. During a creation phase, letters can be added to or removed from the alphabet. If the final set of letters has been created, the alphabet has to be finished. Afterwards no further changes are accepted. The letters are lexicographically ordered in the alphabet.

Remark: This data type is experimental. It can significantly change in future versions.

```
#include < LEDA/string/alphabet.h >
```

2. Creation

alphabet *A*; creates an instance *A* of type *alphabet*.

alphabet *A*(*const string seq*);

creates an instance *A* of type *alphabet* and initializes *A* to be the set of all different letters in *seq*. The alphabet is set to be finished by this constructor.

3. Operations

void *A*.setStandard();

sets the standard alphabet consisting of the upper case letters A-Z and finishes the alphabet construction phase.

<i>bool</i>	<i>A.isStandard()</i>	returns true if the alphabet consists of the upper case letters A-Z, false otherwise.
<i>void</i>	<i>A.setDNA()</i>	sets the alphabet to the set consisting of the letters A,C,T, and G and finishes the alphabet construction phase.
<i>bool</i>	<i>A.isDNA()</i>	returns true if the alphabet consists of the letters A,C,T, and G.
<i>void</i>	<i>A.addLetter(char ch)</i>	adds letter <i>ch</i> to <i>A</i> . <i>Precondition:</i> <i>A</i> is not yet finished. If it is finished, an exception is thrown.
<i>void</i>	<i>A.delLetter(char ch)</i>	deletes letter <i>ch</i> from <i>A</i> if contained; otherwise, nothing happens. <i>Precondition:</i> <i>A</i> is not yet finished. If it is finished, an exception is thrown.
<i>char</i>	<i>A.getLetter(unsigned i)</i>	returns the letter at position <i>i</i> of the lexicographically ordered set of letters, starting with position 0. If <i>i</i> is too big, an exception is thrown. <i>Precondition:</i> <i>A</i> is finished. Otherwise an exception is thrown.
<i>void</i>	<i>A.setFinished()</i>	finishes the alphabet.
<i>bool</i>	<i>A.getFinished()</i>	returns <i>true</i> if <i>A</i> is finished, <i>false</i> otherwise.
<i>bool</i>	<i>A.isFinished()</i>	returns <i>true</i> if <i>A</i> is finished, <i>false</i> otherwise.
<i>string</i>	<i>A.getLetters()</i>	returns a string containing all letters of <i>A</i> in lexicographical order. <i>Precondition:</i> <i>A</i> is finished. Otherwise an exception is thrown.
<i>int</i>	<i>A.getLength()</i>	returns the size of <i>A</i> , that is the number of different letters in <i>A</i> . <i>Precondition:</i> <i>A</i> is finished. Otherwise an exception is thrown.
<i>int</i>	<i>A.getSize()</i>	same as <i>getLength()</i> .

5.2 String Matching Algorithms (*string_matching*)

1. Definition

An instance *M* of the data type *string_matching* is an object maintaining a pattern and a string. It provides a collection of different algorithms for computation of the exact string matching problem. Each function computes a list of all starting positions of occurrences of the pattern in the string.

The algorithms can be called explicitly by their name or implicitly by making an algorithm the "current" algorithm (specified by the *setAlgorithm*-method) and using functions *getFirstOccurrence()*, *getNextOccurrence()*, and *getAllOccurrences()*.

Here is the list of the available parameters to specify the algorithm in the *setAlgorithm(alg)*-method. For each algorithm, the enumeration index gives the corresponding *int* that can be used in the *setAlgorithm(int)*-method in order to specify the algorithm.

1. *KARP_RABIN*
2. *MORRIS_PRATT*
3. *KNUTH_MORRIS_PRATT*
4. *GALIL_SEIFERAS*
5. *BOYER_MOORE*
6. *TURBO_BOYER_MOORE*
7. *TUNED_BOYER_MOORE*
8. *ZHU_TAKAOKA*
9. *BERRY_RAVINDRAN*
10. *SMITH*
11. *RAITA*
12. *HORSPOOL*
13. *BRUTE_FORCE*
14. *SHIFT_OR*
15. *REVERSE_COLUSSI*
16. *QUICK_SEARCH*

- 17. *REVERSE_FACTOR*
- 18. *TURBO_REVERSE_FACTOR*
- 19. *OPTIMAL_MISMATCH*

Remark: This data type is experimental. It can significantly change in future versions.

```
#include < LEDA/string/string_matching.h >
```

2. Creation

string_matching *M*; creates an instance *M* of type *string_matching*.

string_matching *M*(*const string& s1*, *const string& s2*);
 creates an instance *M* of type *string_matching* and initializes the
 pattern to *s1* and the string to *s2*.

3. Operations

void *M*.setPattern(*const string& str*)
 sets the pattern to *str*.

void *M*.setString(*const string& str*)
 sets the string to *str*.

string *M*.getPattern()
 returns the pattern.

string *M*.getString()
 returns the string.

void *M*.setStrings(*const string& str1*, *const string& str2*)
 sets the pattern to *str1* and the string to *str2*.

void *M*.setAlgorithm(*alg A*) sets the current algorithm to *A* (see table above).

void *M*.setAlgorithm(*int A*) sets the current algorithm to *A* by index (see table above).

list<int> *M*.getAllOccurences()
 executes the current algorithm reporting all occurences
 of the pattern in the string.

int *M*.getFirstOccurence()
 executes the current algorithm reporting the first oc-
 currence of the pattern in the string. If there is none,
 -1 is returned.

int *M*.getNextOccurence(*int i*)
 executes the current algorithm reporting the first oc-
 currence after position *i* of the pattern in the string. If
 there is none, -1 is returned. String positions start with
 0.

<i>list<int></i> <i>M.getResult()</i>	returns the list of results after a computation.
<i>void</i> <i>M.karp_rabin()</i>	applies the algorithm of Karp and Rabin.
<i>void</i> <i>M.morris_pratt()</i>	applies the algorithm of Morris and Pratt.
<i>void</i> <i>M.knuth_morris_pratt()</i>	applies the algorithm of Knuth, Morris and Pratt.
<i>void</i> <i>M.galilseiferas()</i>	applies the algorithm of Galil and Seiferas.
<i>void</i> <i>M.boyer_moore()</i>	applies the algorithm of Boyer and Moore.
<i>void</i> <i>M.turbo_boyer_moore()</i>	applies the turbo algorithm of Boyer and Moore.
<i>void</i> <i>M.tuned_boyer_moore()</i>	applies the tuned algorithm of Boyer and Moore.
<i>void</i> <i>M.zhu_takaoka()</i>	applies the algorithm of Zhu and Takaoka.
<i>void</i> <i>M.berry_ravindran()</i>	applies the algorithm of Berry and Ravindran.
<i>void</i> <i>M.smith()</i>	applies the algorithm of Smith.
<i>void</i> <i>M.raita()</i>	applies the algorithm of Raita.
<i>void</i> <i>M.horspool()</i>	applies the algorithm of Horspool.
<i>void</i> <i>M.brute_force()</i>	applies the naive brute force algorithm.
<i>void</i> <i>M.shift_or()</i>	applies the shift-or algorithm.
<i>void</i> <i>M.reverse_colussi()</i>	applies the reverse colussi algorithm.
<i>void</i> <i>M.quick_search()</i>	applies the quick search algorithm.
<i>void</i> <i>M.reverse_factor()</i>	applies the reverse factor algorithm.
<i>void</i> <i>M.turbo_reverse_factor()</i>	applies the turbo reverse colussi algorithm.
<i>void</i> <i>M.optimal_mismatch()</i>	applies the optimal mismatch algorithm.

5.3 Score Matrix (`score_matrix`)

1. Definition

An instance S of the data type `score_matrix` is an object required by alignment computations. The object contains an alphabet representing residues and maintains a table that assigns a score to any pair of aligned residues. In addition it maintains the gap penalty values.

Remark: This data type is experimental. It can significantly change in future versions.

```
#include < LEDA/string/score_matrix.h >
```

2. Creation

```
score_matrix S(int defmatch = 1, int defmismatch = -1);
```

creates an instance S of type `score_matrix`. The alphabet is set to the standard alphabet consisting of the capital letters A - Z. The scores are initialized to `defmatch` if the letters are identical (1 by default), to `defmismatch` otherwise (-1 by default).

```
score_matrix S(alphabet& alt, int defmatch = 1, int defmismatch = -1);
```

creates an instance S of type `score_matrix`. The alphabet is set to `alt`. The scores are initialized to `defmatch` if the letters are identical (1 by default), to `defmismatch` otherwise (-1 by default).

3. Operations

```
void S.setScore(char a, char b, int sc)
```

sets the score for a and b to sc .

Precondition: a and b are in the score alphabet. Otherwise an exception is thrown.

```
int S.getScore(char a, char b) returns the score for  $a$  and  $b$ .
```

Precondition: a and b are in the score alphabet. Otherwise an exception is thrown.

```
bool S.hasScore(char a, char b) returns bool if score is defined for  $a$  and  $b$ , otherwise false.
```

```
void S.setScoreMatch(int sc) sets the score for all pairs  $a$  and  $a$  to  $sc$ .
```

```
void S.setScoreMismatch(int sc)
```

sets the score for all pairs a and b with $a \neq b$ to sc .

```
void S.setGapPenalty(int pen) sets the penalty for starting a new gap to  $pen$ .
```

void *S.setGapIncPenalty(int incpen)*

sets the penalty for extending a gap by one position to *incpen*.

void *S.setGapPenalty(int pen, int incpen)*

sets the penalty for starting a new gap to *pen* and for extending a gap by 1 position to *incpen*.

int *S.getGapPenalty()*

returns the penalty for starting a new gap.

int *S.getGapIncPenalty()*

returns the penalty for extending a gap by one position.

5.4 String Distance Function (`distance`)

1. Definition

An instance D of the data type *distance* is an object maintaining two strings and providing several string distance functions.

The Hamming distance between two strings of equal length is the number of positions for which the corresponding symbols are different.

The Levenshtein distance or edit distance between two strings is given by the minimum number of operations needed to transform one string into the other, where an operation is an insertion, deletion, or substitution of a single character.

The General Levenshtein distance is given by the minimum sum of the costs over a sequence of operations needed to transform one string into the other, where operation is an insertion, deletion, or substitution and a cost is assigned to each of the operations.

The Damerau-Levenshtein distance is an extension of Levenshtein distance that counts transposition as a single edit operation. Strictly speaking, the Damerau-Levenshtein distance is equal to the minimal number of insertions, deletions, substitutions and transpositions needed to transform one string into the other.

The algorithms can be called explicitly by their name or implicitly by making an algorithm the "current" algorithm (method *setAlgorithm(.)*) and using the *run()*-method.

Here is the list of the available parameters to specify the algorithm in the *setAlgorithm(alg)*-method in order to call it by the *run()*-method. For each algorithm, the enumeration index gives the corresponding *int* that can be used in the *setAlgorithm(int)*-method in order to specify the algorithm.

1. *HAMMING*
2. *LEVENSHTEIN*
3. *DAMERAU_LEVENSHTEIN*
4. *GENERAL_LEVENSHTEIN*

Remark: This data type is experimental. It can significantly change in future versions.

```
#include < LEDA/string/distance.h >
```

2. Creation

```
distance  $D$ ;                    creates an instance  $D$  of type distance.
```

```
distance  $D$ (const string&  $s1$ , const string&  $s2$ );  
                                 creates an instance  $D$  of type distance and initializes the two strings  
                                 to  $s1$  resp.  $s2$ .
```

3. Operations

<i>int</i>	<i>D.hamming()</i>	returns the Hamming distance of two strings. If the strings have different lengths, -1 is returned.
<i>int</i>	<i>D.levenshtein()</i>	returns the Levenshtein distance of two strings.
<i>int</i>	<i>D.damerau_levenshtein()</i>	returns the Damerau Levenshtein distance of two strings.
<i>unsigned int</i>	<i>D.general_levenshtein()</i>	returns the General Levenshtein distance of two strings.
<i>void</i>	<i>D.setAlgorithm(alg A)</i>	sets the current algorithm to <i>A</i> (see table above).
<i>void</i>	<i>D.setAlgorithm(int A)</i>	sets the current algorithm to <i>A</i> by index (see table above).
<i>int</i>	<i>D.run()</i>	executes the current algorithm.
<i>void</i>	<i>D.setFirstString(const string& str)</i>	assigns <i>str</i> to the first string.
<i>void</i>	<i>D.setSecondString(const string& str)</i>	assigns <i>str</i> to the second string.
<i>string</i>	<i>D.getFirstString()</i>	returns first string.
<i>string</i>	<i>D.getSecondString()</i>	returns second string.

5.5 Alignment Functions (`alignment`)

1. Definition

An instance *A* of the data type *alignment* is an object maintaining two strings, a *score_matrix*, a penalty value for starting a gap and a penalty value for extending an already started gap. It provides several functions for global and local alignment computation. The result of an alignment computation is stored in the object.

Remark: This data type is experimental. It can significantly change in future versions.

```
#include < LEDA/string/alignment.h >
```

2. Creation

alignment *A*; creates an instance *A* of type *alignment*.

alignment *A*(*const score_matrix& score*);
 creates an instance *A* of type *alignment* and initializes the score
 matrix to *score*.

alignment *A*(*const score_matrix& score, const string& s1, const string& s2*);
 creates an instance *A* of type *alignment* and initializes the score
 matrix to *score*, and the strings to *s1* and *s2*.

alignment *A*(*const string& s1, const string& s2*);
 creates an instance *A* of type *alignment* and initializes the strings
 to *s1* and *s2*.

3. Operations

void *A*.setStringA(*const string& x*)
 sets the first string to *x*.

void *A*.setStringB(*const string& x*)
 sets the second string to *x*.

string *A*.getStringA()
 returns the first string.

string *A*.getStringB()
 returns the second string.

string *A*.getAIA()
 returns the first alignment string, that is the first string
 with its gaps after an alignment computation.

string *A*.getAIB()
 returns the second alignment string, that is the second
 string with its gaps after an alignment computation.

- string* *A*.getAllInfo() shows the correspondence information for each position in the two alignment strings. Its *i*-th position is *"/*", if the letters are identical, *"X"* if they are different but they are matched and *" "* if there is a gap in one of the alignment strings.
- void* *A*.setGapPenalty(*int* *x*) sets the penalty for a gap to *x*.
- void* *A*.setGapIncPenalty(*int* *x*) sets the penalty for extending an existing gap by one position to *x*.
- int* *A*.getGapPenalty() returns the penalty for a gap.
- int* *A*.getGapIncPenalty() returns the penalty for a gap extension of one position.
- void* *A*.globalLw() runs a global alignment algorithm based on Needleman and Wunsch, where there is a penalty *x* for each gap proportional to its length. *x* can be set by *setGapPenalty*. The algorithm requires quadratic space.
- void* *A*.localLw() runs a local alignment algorithm based on Smith and Waterman, where there is a penalty *x* for each gap proportional to its length. *x* can be set by *setGapPenalty*. The algorithm requires quadratic space.
- void* *A*.globalLaffLw() runs a global alignment algorithm based on Needleman and Wunsch, where there is a penalty $x + k * y$ for each gap, where *k* is the length of the gap. *x* can be set by *setGapPenalty* and *y* by *setGapIncPenalty*. The algorithm requires quadratic space.
- void* *A*.localLaffLw() runs a local alignment algorithm based on Smith and Waterman, where there is a penalty $x + k * y$ for each gap, where *k* is the length of the gap. *x* can be set by *setGapPenalty* and *y* by *setGapIncPenalty*. The algorithm requires quadratic space.
- unsigned int* *A*.longest_common_substring() returns the length of the longest common substring of the two strings.
- unsigned int* *A*.longest_common_subsequence() returns the length of the longest common subsequence of the two strings and stores them aligned in the alignment strings.

Chapter 6

Number Types and Linear Algebra

6.1 Integers of Arbitrary Length (`integer`)

1. Definition

An instance of the data type *integer* is an integer number of arbitrary length. The internal representation of an integer consists of a vector of so-called *digits* and a sign bit. A *digit* is an unsigned long integer (type *unsigned long*).

```
#include < LEDA/numbers/integer.h >
```

2. Creation

`integer a;` creates an instance *a* of type *integer* and initializes it with zero.

`integer a(int n);` creates an instance *a* of type *integer* and initializes it with the value of *n*.

`integer a(unsigned int i);`
creates an instance *a* of type *integer* and initializes it with the value of *i*.

`integer a(long l);` creates an instance *a* of type *integer* and initializes it with the value of *l*.

`integer a(unsigned long i);`
creates an instance *a* of type *integer* and initializes it with the value of *i*.

`integer a(double x);` creates an instance *a* of type *integer* and initializes it with the integral part of *x*.

`integer a(unsigned int sz, const digit * vec, int sign = 1);`
creates an instance *a* of type *integer* and initializes it with the value represented by the first *sz* digits *vec* and the *sign*.

integer *a*(*const char * s*);

a creates an instance *a* of type *integer* from its decimal representation given by the string *s*.

integer *a*(*const string& s*);

a creates an instance *a* of type *integer* from its decimal representation given by the string *s*.

3. Operations

The arithmetic operations $+$, $-$, $*$, $/$, $+$ =, $-$ =, $*$ =, $/$ =, $-$ (unary), $++$, $--$, the modulus operation ($\%$, $\% =$), bitwise AND ($\&$, $\& =$), bitwise OR ($|$, $| =$), the complement (\sim), the shift operations (\ll , \gg), the comparison operations $<$, $< =$, $>$, $> =$, $==$, $!=$ and the stream operations all are available.

<i>int</i>	<i>a</i> .sign()	returns the sign of <i>a</i> .
<i>int</i>	<i>a</i> .length()	returns the number of bits of the representation of <i>a</i> .
<i>bool</i>	<i>a</i> .is_long()	returns whether <i>a</i> fits in the data type <i>long</i> .
<i>long</i>	<i>a</i> .to_long()	returns a <i>long</i> number which is initialized with the value of <i>a</i> . <i>Precondition</i> : <i>a</i> .is_long() is <i>true</i> .
<i>double</i>	<i>a</i> .to_double()	returns a double floating point approximation of <i>a</i> .
<i>double</i>	<i>a</i> .to_double(<i>bool& is_double</i>)	as above, but also returns in <i>is_double</i> whether the conversion was exact.
<i>double</i>	<i>a</i> .to_float()	as above.
<i>string</i>	<i>a</i> .to_string()	returns the decimal representation of <i>a</i> .
<i>integer&</i>	<i>a</i> .from_string(<i>string s</i>)	sets <i>a</i> to the number that has decimal representation <i>s</i> .
<i>sz_t</i>	<i>a</i> .used_words()	returns the length of the digit vector that represents <i>a</i> .
<i>digit</i>	<i>a</i> .highword()	returns the most significant digit of <i>a</i> .
<i>digit</i>	<i>a</i> .contents(<i>int i</i>)	returns the <i>i</i> -th digit of <i>a</i> (the first digit is <i>a</i> .contents(0)).
<i>void</i>	<i>a</i> .hex_print(<i>ostream& o</i>)	prints the digit vector that represents <i>a</i> in hex format to the output stream <i>o</i> .
<i>bool</i>	<i>a</i> .iszero()	returns whether <i>a</i> is equal to zero.

Non-member functions

<i>double</i>	<code>to_double(const integer& a)</code>	returns a double floating point approximation of <i>a</i> .
<i>integer</i>	<code>sqrt(const integer& a)</code>	returns the largest <i>integer</i> which is not larger than the square root of <i>a</i> .
<i>integer</i>	<code>abs(const integer& a)</code>	returns the absolute value of <i>a</i> .
<i>integer</i>	<code>factorial(const integer& n)</code>	returns <i>n!</i> .
<i>integer</i>	<code>gcd(const integer& a, const integer& b)</code>	returns the greatest common divisor of <i>a</i> and <i>b</i> .
<i>int</i>	<code>log(const integer& a)</code>	returns the logarithm of <i>a</i> to the basis 2 (rounded down).
<i>int</i>	<code>log2abs(const integer& a)</code>	returns the logarithm of $ a $ to the basis 2 (rounded up).
<i>int</i>	<code>sign(const integer& a)</code>	returns the sign of <i>a</i> .
<i>integer</i>	<code>sqr(const integer& a)</code>	returns a^2 .
<i>double</i>	<code>double_quotient(const integer& a, const integer& b)</code>	returns a the best possible floating-point approximation of a/b .
<i>integer</i>	<code>integer::random(int n)</code>	returns a random integer of length <i>n</i> bits.

4. Implementation

An *integer* is essentially implemented by a vector *vec* of *unsigned long* numbers. The sign and the size are stored in extra variables. Some time critical functions are also implemented in assembler code.

6.2 Rational Numbers (`rational`)

1. Definition

An instance q of type *rational* is a rational number where the numerator and the denominator are both of type *integer*.

```
#include <LEDA/numbers/rational.h >
```

2. Creation

rational q ; creates an instance q of type *rational*.

rational $q(\text{integer } n)$;
 creates an instance q of type *rational* and initializes it with the integer n .

rational $q(\text{integer } n, \text{integer } d)$;
 creates an instance q of type *rational* and initializes it to the rational number n/d .

rational $q(\text{double } x)$;
 creates an instance q of type *rational* and initializes it with the value of x .

3. Operations

The arithmetic operations $+$, $-$, $*$, $/$, $+$ =, $-$ =, $*$ =, $/$ =, $-$ (unary), $++$, $--$, the comparison operations $<$, $<=$, $>$, $>=$, $==$, $!=$ and the stream operations are all available.

void $q.\text{negate}()$ negates q .

void $q.\text{invert}()$ inverts q .

rational $q.\text{inverse}()$ returns the inverse of q .

integer $q.\text{numerator}()$ returns the numerator of q .

integer $q.\text{denominator}()$ returns the denominator of q .

rational& $q.\text{simplify}(\text{const integer\& } a)$
 simplifies q by a .
 Precondition: a divides the numerator and the denominator of q .

rational& $q.\text{normalize}()$ normalizes q .

double to_float() returns a double floating point approximation of q . If the q is approximable by a *normalized, finite* floating point number, the error is 3ulps, i.e., three units in the last place.

string q.to_string() returns a string representation of q .

Non-member functions

int sign(const rational& q) returns the sign of q .

rational abs(const rational& q) returns the absolute value of q .

rational sqr(const rational& q) returns the square of q .

integer trunc(const rational& q) returns the *integer* with the next smaller absolute value.

rational pow(const rational& q, int n) returns the n -th power of q .

rational pow(const rational& q, integer a) returns the a -th power of q .

integer floor(const rational& q) returns the next smaller *integer*.

integer ceil(const rational& q) returns the next bigger *integer*.

integer round(const rational& q) rounds q to the nearest *integer*.

rational smallRationalBetween(const rational& p, const rational& q) returns a rational number between p and q whose denominator is as small as possible.

rational smallRationalNear(const rational& p, rational eps) returns a rational number between $p - eps$ and $p + eps$ whose denominator is as small as possible.

4. Implementation

A *rational* is implemented by two *integer* numbers which represent the numerator and the denominator. The sign is represented by the sign of the numerator.

6.3 The data type `bigfloat` (`bigfloat`)

1. Definition

In general a *bigfloat* is given by two integers s and e where s is the significant and e is the exponent. The tuple (s, e) represents the real number

$$s \cdot 2^e.$$

In addition, there are the special *bigfloat* values *NaN* (not a number), *pZero*, *nZero* ($= +0, -0$), and *pInf*, *nInf* ($= +\infty, -\infty$). These special values behave as defined by the IEEE floating point standard. In particular, $\frac{5}{+0} = \infty$, $\frac{-5}{+0} = -\infty$, $\infty + 1 = \infty$, $\frac{5}{\infty} = +0$, $+\infty + (-\infty) = \text{NaN}$ and $0 \cdot \infty = \text{NaN}$.

Arithmetic on *bigfloats* uses two parameters: The precision *prec* of the result (in number of binary digits) and the rounding mode *mode*. Possible rounding modes are:

- *TO_NEAREST*: round to the closest representable value
- *TO_ZERO*: round towards zero
- *TO_INF*: round away from zero
- *TO_P_INF*: round towards $+\infty$
- *TO_N_INF*: round towards $-\infty$
- *EXACT*: compute exactly for $+$, $-$, $*$ and round to nearest otherwise

Operations $+$, $-$, $*$ work as follows. First, the exact result z is computed. If the rounding mode is *EXACT* then z is the result of the operation. Otherwise, let s be the significant of the result; s is rounded to *prec* binary places as dictated by *mode*. Operations $/$ and $\sqrt{\quad}$ work accordingly except that *EXACT* is treated as *TO_NEAREST*.

The parameters *prec* and *mode* are either set directly for a single operation or else they are set globally for every operation to follow. The default values are 53 for *prec* and *TO_NEAREST* for *mode*.

```
#include <LEDA/numbers/bigfloat.h >
```

2. Creation

A *bigfloat* may be constructed from data types *double*, *long*, *int* and *integer*, without loss of accuracy. In addition, an instance of type *bigfloat* can be created as follows.

```
bigfloat x(const integer& s, const integer& e);
```

introduces a variable x of type *bigfloat* and initializes it to $s \cdot 2^e$

<i>double</i>	<code>x.to_double()</code>	returns the double value next to x (i.e. rounding mode is always <i>TO_NEAREST</i>).
<i>double</i>	<code>x.to_double(bool& is_double)</code>	as above, but also returns in <i>is_double</i> whether the conversion was exact.
<i>double</i>	<code>x.to_double(double& abs_err, rounding_modes m = TO_NEAREST)</code>	as above, but with more flexibility: The parameter m specifies the rounding mode. For the returned value d , we have $ x - d \leq \text{abs_err}$. (<i>abs_err</i> is zero iff the conversion is exact and the returned value is finite.)
<i>double</i>	<code>x.to_double(rounding_modes m)</code>	as above, but does not return an error bound.
<i>rational</i>	<code>x.to_rational()</code>	converts x into a number of type <i>rational</i> .
<i>sz_t</i>	<code>x.get_significant_length(void)</code>	returns the length of the significant of x .
<i>sz_t</i>	<code>x.get_effective_significant_length(void)</code>	returns the length of the significant of x without trailing zeros.
<i>integer</i>	<code>x.get_exponent(void)</code>	returns the exponent of x .
<i>integer</i>	<code>x.get_significant(void)</code>	returns the significant of x .
<i>sz_t</i>	<code>bigfloat::set_precision(sz_t p)</code>	sets the global arithmetic precision to p binary digits and returns the old value
<i>sz_t</i>	<code>bigfloat::get_precision()</code>	returns the currently active global arithmetic precision
<i>sz_t</i>	<code>bigfloat::set_output_precision(sz_t d)</code>	sets the precision of <i>bigfloat</i> output to d decimal digits and returns the old value
<i>sz_t</i>	<code>bigfloat::set_input_precision(sz_t p)</code>	sets the precision of <i>bigfloat</i> input to p binary digits and returns the old value
<i>rounding_modes</i>	<code>bigfloat::set_rounding_mode(rounding_modes m)</code>	sets the global rounding mode to m and returns the old rounding mode

rounding_modes bigfloat::get_rounding_mode()

returns the currently active global rounding mode

output_modes bigfloat::set_output_mode(output_modes o_mode)

sets the output mode to *o_mode* and returns the old output mode

A *bigfloat* x can be rounded by the call $round(x, prec, mode, is_exact)$. The optional boolean variable *is_exact* is set to true if and only if the rounding operation did not change the value of x .

*integer to_integer(rounding_modes rmode = TO_NEAREST,
bool& is_exact = bigfloat::dbool)*

returns the integer value next to x (in the given rounding mode)

integer to_integer(const bigfloat& x, rounding_modes rmode, bool& is_exact)

returns $x.to_integer(...)$.

3. Operations

The arithmetical operators $+$, $-$, $*$, $/$, $+=$, $-=$, $*=$, $/=$, $sqrt$, the comparison operators $<$, \leq , $>$, \geq , $=$, \neq and the stream operators are available. Addition, subtraction, multiplication, division, square root and power are implemented by the functions *add*, *sub*, *mul*, *div*, *sqrt* and *power* respectively. For example, the call

$$add(x, y, prec, mode, is_exact)$$

computes the sum of bigfloats x and y with *prec* binary digits, in rounding mode *mode*, and returns it. The optional last parameter *is_exact* is a boolean variable that is set to *true* if and only if the returned bigfloat exactly equals the sum of x and y . The parameters *prec* and *mode* are also optional and have the global default values *global_prec* and *round_mode* respectively, that is, the three calls $add(x, y, global_prec, round_mode)$, $add(x, y, global_prec)$, and $add(x, y)$ are all equivalent. The syntax for functions *sub*, *mul*, *div*, and *sqrt* is analogous.

The operators $+$, $-$, $*$, and $/$ are implemented by their counterparts among the functions *add*, *sub*, *mul* and *div*. For example, the call $x + y$ is equivalent to $add(x, y)$.

bool isNaN(const bigfloat& x)

returns *true* if and only if x is in special state *NaN*

bool isnInf(const bigfloat& x)

returns *true* if and only if x is in special state *nInf*

bool ispInf(const bigfloat& x)

returns *true* if and only if x is in special state *pInf*

- bool* `isnZero(const bigfloat& x)`
 returns *true* if and only if x is in special state *nZero*
- bool* `ispZero(const bigfloat& x)`
 returns *true* if and only if x is in special state *pZero*
- bool* `isZero(const bigfloat& x)`
 returns *true* if and only if `ispZero(x)` or `isnZero(x)`
- bool* `isInf(const bigfloat& x)`
 returns *true* if and only if `ispInf(x)` or `isnInf(x)`
- bool* `isSpecial(const bigfloat& x)`
 returns *true* if and only if x is in a special state
- int* `sign(const bigfloat& x)`
 returns the sign of x .
- bigfloat* `abs(const bigfloat& x)`
 returns the absolute value of x
- bigfloat* `ipow2(const integer& p)`
 returns 2^p
- integer* `ilog2(const bigfloat& x)`
 returns the binary logarithm of `abs(x)`, rounded up to the next integer. *Precondition:* $x \neq 0$
- integer* `ceil(const bigfloat& x)`
 returns x , rounded up to the next integer
- integer* `floor(const bigfloat& x)`
 returns x , rounded down to the next integer
- bigfloat* `sqrt_d(const bigfloat& x, sz_t p, int d)`
 returns $\sqrt[d]{x}$, with relative error $\leq 2^{-p}$ but not necessarily exactly rounded to p binary digits
- string* `x.to_string(sz_t dec_prec = global_output_prec)`
 returns the decimal representation of x , rounded to a decimal precision of `dec_prec` decimal places.
- bigfloat& x* `from_string(string s, sz_t bin_prec = global_input_prec)`
 returns an approximation of the decimal number given by the string s by a *bigfloat* that is accurate up to `bin_prec` binary digits
- ostream& ostream& os* `<< const bigfloat& x`
 writes x to output stream os

istream& istream& is \gg *bigfloat& x*

reads x from input stream is in decimal format

6.4 The data type real (real)

1. Definition

An instance x of the data type `real` is a real algebraic number. There are many ways to construct a real: either by conversion from `double`, `bigfloat`, `integer` or `rational`, by applying one of the arithmetic operators $+$, $-$, $*$, $/$ or $\sqrt[n]{}$ to real numbers or by using the \diamond -operator to define a real root of a polynomial over real numbers. One may test the sign of a real number or compare two real numbers by any of the comparison relations $=$, \neq , $<$, \leq , $>$ and \geq . The outcome of such a test is mathematically *exact*. We give consider an example expression to clarify this:

$$x := (\sqrt{17} - \sqrt{12}) * (\sqrt{17} + \sqrt{12}) - 5$$

Clearly, the value of x is zero. But if you evaluate x using double arithmetic you obtain a tiny non-zero value due to rounding errors. If the data type `real` is used to compute x then `sign(x)` yields zero. ¹ There is also a non-standard version of the sign function: the call `x.sign(integer q)` computes the sign of x under the precondition that $|x| \leq 2^{-q}$ implies $x = 0$. This version of the sign function allows the user to assist the data type in the computation of the sign of x , see the example below.

There are several functions to compute approximations of reals. The calls `x.to_bigfloat()` and `x.get_bigfloat_error()` return `bigfloats` `xnum` and `xerr` such that $|xnum - x| \leq xerr$. The user may set a bound on `xerr`. More precisely, after the call `x.improve_approximation_to(integer q)` the data type guarantees $xerr \leq 2^{-q}$. One can also ask for `double` approximations of a real number x . The calls `x.to_double()` and `x.get_double_error()` return `doubles` `xnum` and `xerr` such that $|xnum - x| \leq xerr$. Note that `xerr = ∞` is possible.

```
#include <LEDA/numbers/real.h >
```

2. Types

```
typedef polynomial<real> Polynomial    the polynomial type.
```

3. Creation

reals may be constructed from data types `double`, `bigfloat`, `long`, `int` and `integer`. The default constructor `real()` initializes the real to zero.

4. Operations

```
double x.to_double( )    returns the current double approximation of x.
```

```
double x.to_double(double& error)
                        as above, but also computes a bound on the absolute error.
```

- bigfloat* *x*.to_bigfloat() returns the current bigfloat approximation of *x*.
- double* *x*.get_double_error() returns the *absolute* error of the current double approximation of *x*, i.e., $|x - x.to_double()| \leq x.get_double_error()$.
- bigfloat* *x*.get_bigfloat_error() returns the absolute error of the current bigfloat approximation of *x*, i.e., $|x - x.to_bigfloat()| \leq x.get_bigfloat_error()$.
- bigfloat* *x*.get_lower_bound() returns the lower bound of the current interval approximation of *x*.
- bigfloat* *x*.get_upper_bound() returns the upper bound of the current interval approximation of *x*.
- rational* *x*.high() returns a rational upper bound of the current interval approximation of *x*.
- rational* *x*.low() returns a rational lower bound of the current interval approximation of *x*.
- double* *x*.get_double_lower_bound() returns a *double* lower bound of *x*.
- double* *x*.get_double_upper_bound() returns a *double* upper bound of *x*.
- bool* *x*.possible_zero() returns true if 0 is in the current interval approximation of *x*.
- integer* *x*.separation_bound() returns the separation bound of *x*.
- integer* *x*.sep_bfmss() returns the k-ary BFMSS separation bound of *x*.
- integer* *x*.sep_degree_measure() returns the degree measure separation bound of *x*.
- integer* *x*.sep_liyap() returns the Li / Yap separation bound of *x*.
- void* *x*.print_separation_bounds() prints the different separation bounds of *x*.
- bool* *x*.is_general() returns true if the expression defining *x* contains a \diamond -operator, false otherwise.
- bool* *x*.is_rational() returns true if the expression is rational, false otherwise.

- rational* x .to_rational() returns the rational number given by the expression.
Precondition: *is_rational*() has is true.
- int* x .compare(const real& y)
returns the sign of x-y.
- int* compare_all(const growing_array<real>& R, int& j)
compares all elements in R . It returns i such that $R[i] = R[j]$ and $i \neq j$. Precondition: Only two of the elements in R are equal. [Experimental]
- int* x .sign() returns the sign of (the exact value of) x .
- int* x .sign(const integer& q)
as above. Precondition: The user guarantees that $|x| \leq 2^{-q}$ is only possible if $x = 0$. This advanced version of the *sign* function should be applied only by the experienced user. It gives an improvement over the plain *sign* function only in some cases.
- void* x .improve_approximation_to(const integer& q)
recomputes the approximation of x if necessary; the resulting error of the *bigfloat* approximation satisfies x .get_bigfloat_error() $\leq 2^{-q}$
- void* x .compute_with_precision(long k)
recomputes the *bigfloat* approximation of x , if necessary; each numerical operation is carried out with a mantissa length of k . Note that here the size of the resulting x .get_bigfloat_error() cannot be predicted in general.
- void* x .guarantee_relative_error(long k)
recomputes an approximation of x , if necessary; the relative error of the resulting *bigfloat* approximation is less than 2^{-k} , i.e., x .get_bigfloat_error() $\leq |x| \cdot 2^{-k}$.
- ostream& ostream& O* \ll const real& x
writes the closest interval that is known to contain x to the output stream O . Note that the exact representation of x is lost in the stream output.
- istream& istream& I* \gg real& x
reads x number x from the output stream I in *double* format. Note that stream input is currently impossible for more general types of *reals*.

real `sqrt(const real& x)`

$$\sqrt{x}$$

real `root(const real& x, int d)`

$$\sqrt[d]{x}, \text{ precondition: } d \geq 2$$

Note: The functions *real_roots* and *diamond* below are all *experimental* if they are applied to a polynomial which is not square-free.

int `realroots(const Polynomial& P, list<real>& roots, algorithm_type algorithm, bool is_squarefree)`

returns all real roots of the polynomial *P*.

int `realroots(const Polynomial& P, growing_array<real>& roots, algorithm_type algorithm, bool is_squarefree)`

same as above.

int `realroots(const int_Polynomial& iP, list<real>& roots, algorithm_type algorithm = isolating_algorithm, bool is_squarefree = true)`

returns all real roots of the polynomial *iP*.

real `diamond(int j, const Polynomial& P, algorithm_type algorithm, bool is_squarefree)`

returns the *j*-th smallest real root of the polynomial *P*.

real `diamond(rational l, rational u, const Polynomial& P, algorithm_type algorithm, bool is_squarefree)`

returns the real root of the polynomial *P* which is in the isolating interval [*l*,*u*].

real `diamondshort(rational l, rational u, const Polynomial& P, algorithm_type algorithm, bool is_squarefree)`

returns the real root of the polynomial *P* which is in the isolating interval [*l*,*u*].

Precondition: $(u - l) < 1/4$

real `diamond(int j, const int_Polynomial& iP, algorithm_type algorithm = isolating_algorithm, bool is_squarefree = true)`

returns the *j*-th smallest real root of the polynomial *iP*.

real `diamond(rational l, rational u, const int_Polynomial& iP, algorithm_type algorithm = isolating_algorithm, bool is_squarefree = true)`

returns the real root of the polynomial *iP* which is in the isolating interval [*l*,*u*].

real `abs(const real& x)`

absolute value of *x*

real `sqr(const real& x)` square of x

real `dist(const real& x, const real& y)`
 euclidean distance of point (x,y) to the origin

real `powi(const real& x, int n)`
 x^n , i.e., n .th power of x

integer `floor(const real& x)`
 returns the largest integer smaller than or equal to x .

integer `ceil(const real& x)`
 returns the smallest integer greater than or equal to x .

rational `smallRationalBetween(const real& x, const real& y)`
 returns a rational number between x and y with the smallest available denominator. Note that the denominator does not need to be strictly minimal over all possible rationals.

rational `smallRationalNear(const real& x, double eps)`
 returns `small_rational_between(x - eps, x + eps)`.

5. Implementation

A real is represented by the expression which defines it and an *interval* inclusion I that contains the exact value of the real. The arithmetic operators $+$, $-$, $*$, $\sqrt{\quad}$ take constant time. When the sign of a real number needs to be determined, the data type first computes a number q , if not already given as an argument to *sign*, such that $|x| \leq 2^{-q}$ implies $x = 0$. The bound q is computed as described in [79]. Using *bigfloat* arithmetic, the data type then computes an interval I of maximal length 2^{-q} that contains x . If I contains zero, then x itself is equal to zero. Otherwise, the sign of any point in I is returned as the sign of x .

Two shortcuts are used to speed up the computation of the sign. Firstly, if the initial *interval* approximation already suffices to determine the sign, then no *bigfloat* approximation is computed at all. Secondly, the *bigfloat* approximation is first computed only with small precision. The precision is then roughly doubled until either the sign can be decided (i.e., if the current approximation interval does not contain zero) or the full precision 2^{-q} is reached. This procedure makes the *sign* computation of a *real* number x *adaptive* in the sense that the running time of the *sign* computation depends on the complexity of x .

6. Example

We give two typical examples for the use of the data type *real* that arise in Computational geometry. We admit that a certain knowledge about Computational geometry is required for their full understanding. The examples deal with the Voronoi diagram of line segments and the intersection of line segments, respectively.

The following incircle test is used in the computation of Voronoi diagrams of line segments [17, 14]. For i , $1 \leq i \leq 3$, let $l_i : a_i x + b_i y + c_i = 0$ be a line in two-dimensional space and let $p = (0, 0)$ be the origin. In general, there are two circles passing through p and touching l_1 and l_2 . The centers of these circles have homogeneous coordinates (x_v, y_v, z_v) , where

$$\begin{aligned} x_v &= a_1 c_2 + a_2 c_1 \pm \text{sign}(s) \sqrt{2c_1 c_2 (\sqrt{N} + D)} \\ y_v &= b_1 c_2 + b_2 c_1 \pm \text{sign}(r) \sqrt{2c_1 c_2 (\sqrt{N} - D)} \\ z_v &= \sqrt{N} - a_1 a_2 - b_1 b_2 \end{aligned}$$

and

$$\begin{aligned} s &= b_1 D_2 - b_2 D_1, & N &= (a_1^2 + b_1^2)(a_2^2 + b_2^2) \\ r &= a_1 D_2 - a_2 D_1, & D &= a_1 a_2 - b_1 b_2. \end{aligned}$$

Let us concentrate on one of these (say, we take the plus sign in both cases). The test whether l_3 intersects, touches or misses the circle amounts to determining the sign of

$$E := \text{dist}^2(v, l_3) - \text{dist}^2(v, p) = \frac{(a_3 x_v + b_3 y_v + c_3)^2}{a_3^2 + b_3^2} - (x_v^2 + y_v^2).$$

The following program computes the sign of $\tilde{E} := (a_3^2 + b_3^2) \cdot E$ using our data type real.

```

int INCIRCLE( real a1, real b1, real c1, real a2, real b2, real c2, real a3, real b3,
real c3 )
{
  real RN = sqrt((a1 * a1 + b1 * b1) * (a2 * a2 + b2 * b2));
  real RN1 = sqrt(a1 * a1 + b1 * b1);
  real RN2 = sqrt(a2 * a2 + b2 * b2);
  real A = a1 * c2 + a2 * c1;
  real B = b1 * c2 + b2 * c1;
  real C = 2 * c1 * c2;
  real D = a1 * a2 - b1 * b2;
  real s = b1 * RN2 - b2 * RN1;
  real r = a1 * RN2 - a2 * RN1;
  int sign_x = sign(s);
  int sign_y = sign(r);
  real x_v = A + sign_x * sqrt(C * (RN + D));
  real y_v = B - sign_y * sqrt(C * (RN - D));
  real z_v = RN - (a1 * a2 + b1 * b2);
  real P = a3 * x_v + b3 * y_v + c3 * z_v;
  real D3^2 = a3 * a3 + b3 * b3;
  real R^2 = x_v * x_v + y_v * y_v;
  real E = P * P - D3^2 * R^2;
  return sign(E);
}

```

We can make the above program more efficient if all coefficients a_i, b_i and c_i , $1 \leq i \leq 3$, are k bit integers, i.e., integers whose absolute value is bounded by $2^k - 1$. In [17, 14] we showed that for $\tilde{E} \neq 0$ we have $|\tilde{E}| \geq 2^{-24k-26}$. Hence we may add a parameter *int* k in the above program and replace the last line by

return $E.\text{sign}(24 * k + 26)$.

Without this assistance, *reals* automatically compute a weaker bound of $|\tilde{E}| \geq 2^{-56k-161}$ for $\tilde{E} \neq 0$ by [15].

We turn to the line segment intersection problem next. Assume that all endpoints have k -bit integer homogeneous coordinates. This implies that the intersection points have homogeneous coordinates (X, Y, W) where X, Y and W are $(4k + 3)$ - bit integers. The Bentley–Ottmann plane sweep algorithm for segment intersection [65] needs to sort points by their x -coordinates, i.e., to compare fractions X_1/W_1 and X_2/W_2 where X_1, X_2, W_1, W_2 are as above. This boils down to determining the sign of the $8k + 7$ bit integer $X_1 * W_2 - X_2 * W_1$. If all variables X_i, W_i are declared *real* then their sign test will be performed quite efficiently. First, an *interval* approximation is computed and then, if necessary, *bigfloat* approximations of increasing precision. In many cases, the *interval* approximation already determines the sign. In this way, the user of the data type *real* gets nearly the efficiency of a hand-coded floating point filter [35, 66] without any work on his side. This is in marked contrast to [35, 66] and will be incorporated into [65].

6.5 Interval Arithmetic in LEDA (interval)

1. Definition

An instance of the data type *interval* represents a real interval $I = [a, b]$. The basic interval operations $+$, $-$, $*$, $/$, $\sqrt{\quad}$ are available. Type *interval* can be used to approximate exact real arithmetic operations by inexact interval operations, as follows. Each input number x_i is converted into the interval $\{x_i\}$ and all real operations are replaced by interval operations. If x is the result of the exact real calculation and I the interval computed by type *interval*, it is guaranteed that I contains x . I can be seen as a more or less accurate approximation of x . In many cases the computed interval I is small enough to provide a useful approximation of x and the *exact* sign of x . There are four different implementations of *intervals* (consult the implementation section below for details):

- Class *interval_bound_absolute*
- Class *interval_bound_relative*
- Class *interval_round_inside*
- Class *interval_round_outside*, which is usually the fastest but requires that the IEEE754 rounding mode *ieee_positive* is activated, e.g. by using the LEDA class *fpu*.

The interface of all *interval* variants are identical. However, note that the types *interval_round_inside* and *interval_round_outside* are only available on some explicitly supported UNIX platforms, currently including SPARC, MIPS, i386 (PC's compatible to 80386 or higher), and ALPHA. For all platforms, the name *interval* stands for the default implementation *interval_bound_absolute*.

```
#include < LEDA/numbers/interval.h >
```

```
interval x;           creates an instance x of type interval and initializes it with the
                      interval {0}
```

```
interval x(VOLATILE_I double a);
                      creates an instance x of type interval and initializes it with {a}
```

```
interval x(int a);   creates an instance x of type interval and initializes it with {a}
```

```
interval x(long a);  creates an instance x of type interval and initializes it with {a}
```

```
interval x(const integer& a);
                      creates an instance x of type interval and initializes it with the
                      smallest possible interval containing a
```

interval $x(\text{const bigfloat\& } a);$

creates an instance x of type *interval* and initializes it with the smallest possible interval containing a

interval $x(\text{const real\& } a);$

creates an instance x of type *interval* and initializes it with the smallest possible interval containing a

interval $x(\text{const rational\& } a);$

creates an instance x of type *interval* and initializes it with the smallest possible interval containing a

2. Operations

The arithmetic operations $+$, $-$, $*$, $/$, *sqrt*, $+=$, $-=$, $*=$, $/=$ and the stream operators are all available. **Important:** If the advanced implementation *interval_round_outside* is used, the user has to guarantee that for each *interval* operation the IEEE754 rounding mode "towards $+\infty$ " is active. This can be achieved by calling the function *fpu::round_up*(). To avoid side effects with library functions that require the default IEEE754 rounding mode *to_nearest*, the function *fpu::round_nearest*() can be used to reset the rounding mode.

<i>double</i>	$x.\text{to_double}()$	returns the midpoint of the interval x as an approximation for the exact real number represented by x .
<i>double</i>	$x.\text{get_double_error}()$	returns the diameter of the interval x which is the maximal error of the approximation $x.\text{to_double}()$ of the exact real number represented by x .
<i>bool</i>	$x.\text{is_a_point}()$	returns true if and only if the interval x consists of a single point.
<i>bool</i>	$x.\text{is_finite}()$	returns true if and only if the interval x is a finite interval.
<i>bool</i>	$x.\text{contains}(\text{double } x)$	returns true if and only if the interval x contains the number x
<i>double</i>	$x.\text{upper_bound}()$	returns the upper bound of the interval x .
<i>double</i>	$x.\text{lower_bound}()$	returns the lower bound of the interval x .
<i>void</i>	$x.\text{set_range}(\text{VOLATILE_I double } x, \text{VOLATILE_I double } y)$	sets the current interval to $[x, y]$.

<i>void</i>	<code>x.set_midpoint(VOLATILE_I double num, VOLATILE_I double error)</code>	sets the current interval to a superset of $[num - error, num + error]$, i.e., to an interval with midpoint num and radius $error$.
<i>bool</i>	<code>x.sign_is_known()</code>	returns true if and only if all numbers in the interval x have the same sign
<i>int</i>	<code>x.sign()</code>	returns the sign of all numbers in the interval x if this sign is unique; aborts with an error message if <code>x.sign_is_known()</code> gives false

3. Implementation

The types `interval_round_inside` and `interval_round_outside` represent intervals directly by (the negative of) its lower bound and its upper bound as *doubles*. Here all arithmetic operations require that the IEEE754 rounding mode "towards $+\infty$ " is active. For type `interval_round_inside` this is done *inside* each operation, and for type `interval_round_outside` the user has to do this manually "from outside the operations" by an explicit call of `fpu::round_up()`.

The types `interval_bound_absolute` and `interval_bound_relative` represent intervals by their *double* midpoint *NUM* and diameter *ERROR*. The interpretation is that *NUM* is the numerical approximation of a real number and *ERROR* is a bound for the absolute, respectively relative error of *NUM*.

6.6 Modular Arithmetic in LEDA (residual)

1. Definition

The data type *residual* provides an implementation of exact integer arithmetic using modular computation. In contrast to the LEDA type *integer* which offers similar functionality as *residual*, the user of *residual* has to specify for each calculation the maximal bit length b of the integers she wants to be exactly representable by *residuals*. This is done by a call of `residual::set_maximal_bit_length(b)` preceding the calculation. The set of integers in the interval $[-2^b, 2^b)$ is called the *current range* of numbers representable by *residuals*.

A residual number x that is outside the current range is said to *overflow*. As an effect of its overflow, certain operations cannot be applied to x and the result is undefined. These critical operations include e.g. all kinds of conversion, sign testing and comparisons. It is important to realize that for an integer x given by a division-free expression it only matters whether the *final result* x does not overflow. This is sometimes useful and hence overflow is not always checked by default.

Division is available for *residuals*, but with certain restrictions. Namely, for each division x/y the user has to guarantee at least one of the following two conditions:

- `y.is_invertible()` is *true*
- x/y is integral *and* x and y do not overflow.

If the first condition is satisfied, there is an alternative way to do the division x/y . Introducing the residual variable $z = y.inverse()$, the call x/y is equivalent to the call $x*z$. The latter form is advantageous if several divisions have the same divisor y because here the time-consuming inversion of y , which is implicit in the division x/y , has to be performed only once.

If the result of an operation is not integral, the computation will usually proceed without warning. In such cases the computation produces a nonsensical result that is likely to overflow but otherwise is a perfect *residual*. However, the operations mentioned above check for overflow. Note that the implemented overflow checks are not rigorous, detecting invalidity only with empirically high probability. Overflow checking can be switched off by calling `set_maximal_bit_length` with a second, optional parameter `residual::no_overflow_check`.

```
#include < LEDA/numbers/residual.h >
```

6.7 The mod kernel of type residual (residual)

1. Definition

Type *residual::mod* provides the basic modular arithmetic modulo primes of maximal size 2^{26} . Here numbers modulo the prime p are represented by integral doubles in $[0, \dots, p-1]$. This type cannot be instantiated, so there are only static functions and no constructors. The following functions have the common precondition that p is a prime between 2 and 2^{26} .

```
#include < LEDA/numbers/residual.h >
```

2. Operations

- | | | |
|---------------|---|---|
| <i>double</i> | <i>residual::reduce_of_positive(double a, double p)</i> | returns a modulo p for nonnegative integral $0 \leq a < 2^{54}$ |
| <i>double</i> | <i>residual::reduce(double a, double p)</i> | returns a modulo p for any integral a with $ a < 2^{54}$ |
| <i>double</i> | <i>residual::add(double a, double b, double p)</i> | returns $(a + b) \bmod p$ where a, b are integral with $ a , b < 2^{52}$ |
| <i>double</i> | <i>residual::sub(double a, double b, double p)</i> | returns $(a - b) \bmod p$ where a, b are integral with $ a , b < 2^{52}$ |
| <i>double</i> | <i>residual::mul(double a, double b, double p)</i> | returns $(a \cdot b) \bmod p$ where a, b are integral with $ a \cdot b < 2^{53}$ |
| <i>double</i> | <i>residual::div(double a, double b, double p)</i> | returns $(a \cdot b^{-1}) \bmod p$ where a, b are integral with $ a < 2^{26}$ and $b \neq 0 \bmod p$ |
| <i>double</i> | <i>residual::negate(double a, double p)</i> | returns $-a \bmod p$ for nonnegative $a < p$ |
| <i>double</i> | <i>residual::inverse(double a, double p)</i> | returns the inverse of a modulo p for intergal $0 \leq a < p < 2^{32}$ |

6.8 The smod kernel of type residual (residual)

1. Definition

Type *residual::smod* is a variant of class *residual::mod* that uses a *signed* representation. Here numbers modulo p are represented by integral doubles in $(-p/2, +p/2)$. All functions have the common precondition that p is a prime between 3 and 2^{26} . The functions of type *residual::mod* are also provided for class *residual::smod* and have the same meaning, so we do not list them separately here.

```
#include < LEDA/numbers/residual.h >
```

2. Operations

```
double      residual::frac(double a)
```

returns $a + z$ where z is the unique integer such that $a + z \in [-1/2, 1/2)$

3. Creation

```
residual x;          creates an instance  $x$  of type residual and initializes it with zero.
```

```
residual x(long a);  creates an instance  $x$  of type residual and initializes it with the value of  $a$ .
```

```
residual x(int a);   creates an instance  $x$  of type residual and initializes it with the value of  $a$ .
```

```
residual x(double a);
                    creates an instance  $x$  of type residual and initializes it with the integral part of  $x$ .
```

```
residual x(const integer& a);
                    creates an instance  $x$  of type residual and initializes it with the value of  $a$ .
```

4. Operations

```
int      residual::set_maximal_bit_length(int b, bool with_check = do_overflow_check)
                    sets the maximal bit size of the representable numbers to  $b$  and returns the previous maximal bit size
```

```
int      residual::get_maximal_bit_length()
                    returns the maximal bit size of the representable numbers
```

```

void      x.add(const residual& a, const residual& b)
           sets x to  $a + b$ .

void      x.sub(const residual& a, const residual& b)
           sets x to  $a - b$ .

void      x.mul(const residual& a, const residual& b)
           sets x to  $a * b$ .

void      x.div(const residual& a, const residual& b)
           sets x to  $a/b$ .

void      x.det2x2(const residual& a, const residual& b, const residual& c,
                  const residual& d)
           sets x to  $a * d - b * c$ .

void      x.inverse(const residual& a)
           sets x to the modular inverse of a. Precondition:
           x.in_invertible is true.

void      x.negate(const residual& a)
           sets x to  $-a$ .

```

The following functions provide direct read-only access to the internal representation of residual objects. They should only be used by the experienced user after reading the full documentation of type residual.

```

residual_sequence residual::get_primetable()
           returns a copy of the currently used primetable

residual_sequence residual::get_garnertable()
           returns a copy of the currently used table of Garner's
           constants

residual_sequence get_representation()
           returns a copy of the residual sequence representing
           x

```

int `Sign(const floatf& f)`

as described above.

4. Implementation

A *floatf* is represented by a double (its value) and an error bound. An operation on *floatfs* performs the corresponding operation on the values and also computes the error bound for the result. For this reason the cost of a *floatf* operation is about four times the cost of the corresponding operation on doubles. The rules used to compute the error bounds are described in ([65]).

5. Example

see [65] for an application in a sweep line algorithm.

6.10 Double-Valued Vectors (`vector`)

1. Definition

An instance of data type *vector* is a vector of variables of type *double*.

```
#include < LEDA/numbers/vector.h >
```

2. Creation

vector *v*; creates an instance *v* of type *vector*; *v* is initialized to the zero-dimensional vector.

vector *v*(*int d*); creates an instance *v* of type *vector*; *v* is initialized to the zero vector of dimension *d*.

vector *v*(*double a*, *double b*);
 creates an instance *v* of type *vector*; *v* is initialized to the two-dimensional vector (*a*, *b*).

vector *v*(*double a*, *double b*, *double c*);
 creates an instance *v* of type *vector*; *v* is initialized to the three-dimensional vector (*a*, *b*, *c*).

vector *v*(*const vector& w*, *int prec*);
 creates an instance *v* of type *vector*; *v* is initialized to a copy of *w*.
The second argument is for compatibility with *rat_vector*.

3. Operations

int *v*.dim() returns the dimension of *v*.

double& *v*[*int i*] returns *i*-th component of *v*.
Precondition: $0 \leq i \leq v.\text{dim}() - 1$.

double *v*.hcoord(*int i*) for compatibility with *rat_vector*.

double *v*.coord(*int i*) for compatibility with *rat_vector*.

double *v*.sqr.length() returns the square of the Euclidean length of *v*.

double *v*.length() returns the Euclidean length of *v*.

vector *v*.norm() returns *v* normalized.

double *v*.angle(*const vector& w*) returns the angle between *v* and *w*.

<i>vector</i>	<i>v.rotate90(int i = 1)</i>	returns <i>v</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise. <i>Precondition: v.dim() = 2</i>
<i>vector</i>	<i>v.rotate(double a)</i>	returns the <i>v</i> rotated counter-clockwise by an angle of <i>a</i> (in radian). <i>Precondition: v.dim() = 2</i>
<i>vector&</i>	<i>v += const vector& v1</i>	Addition and assign. <i>Precondition: v.dim() = v1.dim().</i>
<i>vector&</i>	<i>v -= const vector& v1</i>	Subtraction and assign. <i>Precondition: v.dim() = v1.dim().</i>
<i>vector</i>	<i>v + const vector& v1</i>	Addition. <i>Precondition: v.dim() = v1.dim().</i>
<i>vector</i>	<i>v - const vector& v1</i>	Subtraction. <i>Precondition: v.dim() = v1.dim().</i>
<i>double</i>	<i>v * const vector& v1</i>	Scalar multiplication. <i>Precondition: v.dim() = v1.dim().</i>
<i>vector</i>	<i>v * double r</i>	Componentwise multiplication with double <i>r</i> .
<i>vector&</i>	<i>v *= double r</i>	multiplies all coordinates by <i>r</i> .
<i>vector</i>	<i>v / double r</i>	Componentwise division which double <i>r</i> .
<i>bool</i>	<i>v == const vector& w</i>	Test for equality.
<i>bool</i>	<i>v != const vector& w</i>	Test for inequality.
<i>void</i>	<i>v.print ostream& O)</i>	prints <i>v</i> componentwise to ostream <i>O</i> .
<i>void</i>	<i>v.print()</i>	prints <i>v</i> to <i>cout</i> .
<i>void</i>	<i>v.read(istream& I)</i>	reads $d = v.dim()$ numbers from input stream <i>I</i> and writes them into $v[0] \dots v[d - 1]$.
<i>void</i>	<i>v.read()</i>	reads <i>v</i> from <i>cin</i> .
<i>ostream&</i>	<i>ostream& O << const vector& v</i>	writes <i>v</i> componentwise to the output stream <i>O</i> .
<i>istream&</i>	<i>istream& I >> vector& v</i>	reads <i>v</i> componentwise from the input stream <i>I</i> .

Additional Operations for vectors in two and three-dimensional space

double *v.xcoord()* returns the zero-th cartesian coordinate of *v*.

<i>double</i>	<code>v.ycoord()</code>	returns the first cartesian coordinate of v .
<i>double</i>	<code>v.zcoord()</code>	returns the second cartesian coordinate of v .
<i>int</i>	<code>compare_by_angle(const vector& v1, const vector& v2)</code>	For a non-zero vector v let $\alpha(v)$ be the angle by which the positive x -axis has to be turned counter-clockwise until it aligns with v . The function compares the angles defined by $v1$ and $v2$, respectively. The zero-vector precedes all non-zero vectors in the angle-order.
<i>vector</i>	<code>cross_product(const vector& v1, const vector& v2)</code>	returns the cross product of the three-dimensional vectors $v1$ and $v2$.

4. Implementation

Vectors are implemented by arrays of real numbers. All operations on a vector v take time $O(v.dim())$, except for `dim` and `[]` which take constant time. The space requirement is $O(v.dim())$.

Be aware that the operations on vectors and matrices incur rounding errors and hence are not completely reliable. For example, if M is a matrix, b is a vector, and x is computed by `x = M.solve(b)` it is not necessarily true that the test `b == M * x` evaluates to true. The types `integer_vector` and `integer_matrix` provide exact linear algebra.

6.11 Double-Valued Matrices (matrix)

1. Definition

An instance of the data type *matrix* is a matrix of variables of type *double*.

```
#include < LEDA/numbers/matrix.h >
```

2. Creation

```
matrix M(int n = 0, int m = 0);
```

creates an instance M of type *matrix*, M is initialized to the $n \times m$ - zero matrix.

```
matrix M(int n, int m, double * D);
```

creates the $n \times m$ matrix M with $M(i, j) = D[i * m + j]$ for $0 \leq i \leq n - 1$ and $0 \leq j \leq m - 1$. *Precondition:* D points to an array of at least $n * m$ numbers of type *double*.

3. Operations

int $M.dim1()$ returns n , the number of rows of M .

int $M.dim2()$ returns m , the number of columns of M .

vector& $M.row(int i)$ returns the i -th row of M (an m -vector).
Precondition: $0 \leq i \leq n - 1$.

vector $M.col(int i)$ returns the i -th column of M (an n -vector).
Precondition: $0 \leq i \leq m - 1$.

matrix $M.trans()$ returns M^T ($m \times n$ - matrix).

matrix $M.inv()$ returns the inverse matrix of M .
Precondition: M is quadratic and $M.det() \neq 0$.

double $M.det()$ returns the determinant of M .
Precondition: M is quadratic.

vector $M.solve(const vector& b)$
returns vector x with $M \cdot x = b$.
Precondition: $M.dim1() == M.dim2() == b.dim()$ and $M.det() \neq 0$.

double& $M(int i, int j)$ returns $M_{i,j}$.
Precondition: $0 \leq i \leq n - 1$ and $0 \leq j \leq m - 1$.

<i>matrix</i>	$M + \text{const matrix\& } M1$	Addition. Precondition: $M.\text{dim1}() == M1.\text{dim1}()$ and $M.\text{dim2}() == M1.\text{dim2}()$.
<i>matrix</i>	$M - \text{const matrix\& } M1$	Subtraction. Precondition: $M.\text{dim1}() == M1.\text{dim1}()$ and $M.\text{dim2}() == M1.\text{dim2}()$.
<i>matrix</i>	$M * \text{const matrix\& } M1$	Multiplication. Precondition: $M.\text{dim2}() == M1.\text{dim1}()$.
<i>vector</i>	$M * \text{const vector\& } vec$	Multiplication with vector. Precondition: $M.\text{dim2}() == vec.\text{dim}()$.
<i>matrix</i>	$M * \text{double } x$	Multiplication with double x.
<i>void</i>	$M.\text{print}(\text{ostream\& } O)$	prints M row by row to ostream O .
<i>void</i>	$M.\text{print}()$	prints M cout.
<i>void</i>	$M.\text{read}(\text{istream\& } I)$	reads $M.\text{dim1}()$ \times $M.\text{dim2}()$ numbers from input stream I and writes them row by row into matrix M .
<i>void</i>	$M.\text{read}()$	prints M from cin.
<i>ostream\&</i>	$\text{ostream\& } O \ll \text{const matrix\& } M$	writes matrix M row by row to the output stream O .
<i>istream\&</i>	$\text{istream\& } I \gg \text{matrix\& } M$	reads a matrix row by row from the input stream I and assigns it to M .

4. Implementation

Data type *matrix* is implemented by two-dimensional arrays of double numbers. Operations *det*, *solve*, and *inv* take time $O(n^3)$, *dim1*, *dim2*, *row*, and *col* take constant time, all other operations take time $O(nm)$. The space requirement is $O(nm)$.

Be aware that the operations on vectors and matrices incur rounding error and hence are not completely reliable. For example, if M is a matrix, b is a vector, and x is computed

by $x = M.solve(b)$ it is not necessarily true that the test $b == M * b$ evaluates to true. The types *integer_vector* and *integer_matrix* provide exact linear algebra.

6.12 Vectors with Integer Entries (`integer_vector`)

1. Definition

An instance of data type *integer_vector* is a vector of variables of type *integer*, the so called ring type. Together with the type *integer_matrix* it realizes the basic operations of linear algebra. Internal correctness tests are executed if compiled with the flag `LA_SELFTEST`.

```
#include < LEDA/numbers/integer_vector.h >
```

2. Creation

integer_vector *v*; creates an instance *v* of type *integer_vector*. *v* is initialized to the zero-dimensional vector.

integer_vector *v*(*int* *d*); creates an instance *v* of type *integer_vector*. *v* is initialized to a vector of dimension *d*.

integer_vector *v*(*const integer&* *a*, *const integer&* *b*);
 creates an instance *v* of type *integer_vector*. *v* is initialized to the two-dimensional vector (*a*, *b*).

integer_vector *v*(*const integer&* *a*, *const integer&* *b*, *const integer&* *c*);
 creates an instance *v* of type *integer_vector*. *v* is initialized to the three-dimensional vector (*a*, *b*, *c*).

integer_vector *v*(*const integer&* *a*, *const integer&* *b*, *const integer&* *c*,
 const integer& *d*);
 creates an instance *v* of type *integer_vector*; *v* is initialized to the four-dimensional vector (*a*, *b*, *c*, *d*).

3. Operations

int *v*.dim() returns the dimension of *v*.

integer& *v*[*int* *i*] returns *i*-th component of *v*.
 Precondition: $0 \leq i \leq v.dim() - 1$.

integer_vector& *v* += *const integer_vector&* *v1*
 Addition plus assignment.
 Precondition: $v.dim() == v1.dim()$.

integer_vector& *v* -= *const integer_vector&* *v1*
 Subtraction plus assignment.
 Precondition: $v.dim() == v1.dim()$.

integer_vector $v + \text{const } \textit{integer_vector}\& v1$

Addition.

Precondition: $v.\textit{dim}() == v1.\textit{dim}()$.

integer_vector $v - \text{const } \textit{integer_vector}\& v1$

Subtraction.

Precondition: $v.\textit{dim}() == v1.\textit{dim}()$.

integer $v * \text{const } \textit{integer_vector}\& v1$

Inner Product.

Precondition: $v.\textit{dim}() == v1.\textit{dim}()$.

integer_vector $\text{const } \textit{integer}\& r * \text{const } \textit{integer_vector}\& v$

Componentwise multiplication with number r .

integer_vector $\text{const } \textit{integer_vector}\& v * \text{const } \textit{integer}\& r$

Componentwise multiplication with number r .

ostream& $\textit{ostream}\& O \ll \text{const } \textit{integer_vector}\& v$

writes v componentwise to the output stream O .

istream& $\textit{istream}\& I \gg \textit{integer_vector}\& v$

reads v componentwise from the input stream I .

4. Implementation

Vectors are implemented by arrays of type *integer*. All operations on a vector v take time $O(v.\textit{dim}())$, except for *dimension* and $[\]$ which take constant time. The space requirement is $O(v.\textit{dim}())$.

6.13 Matrices with Integer Entries (`integer_matrix`)

1. Definition

An instance of data type *integer_matrix* is a matrix of variables of type *integer*, the so called ring type. The arithmetic type *integer* is required to behave like integers in the mathematical sense.

The types *integer_matrix* and *integer_vector* together realize many functions of basic linear algebra. All functions on integer matrices compute the exact result, i.e., there is no rounding error. Most functions of linear algebra are *checkable*, i.e., the programs can be asked for a proof that their output is correct. For example, if the linear system solver declares a linear system $Ax = b$ unsolvable it also returns a vector c such that $c^T A = 0$ and $c^T b \neq 0$. All internal correctness checks can be switched on by the flag `LA_SELFTEST`. Preconditions are checked by default and can be switched off by the compile flag `LEDA_CHECKING_OFF`.

```
#include <LEDA/numbers/integer_matrix.h >
```

2. Creation

```
integer_matrix M(int n, int m);
```

creates an instance M of type *integer_matrix* of dimension $n \times m$.

```
integer_matrix M(int n = 0);
```

creates an instance M of type *integer_matrix* of dimension $n \times n$.

```
integer_matrix M(const array< integer_vector >& A);
```

creates an instance M of type *integer_matrix*. Let A be an array of m column - vectors of common dimension n . M is initialized to an $n \times m$ matrix with the columns as specified by A .

```
integer_matrix integer_matrix::identity(int n)
```

returns an identity matrix of dimension n .

3. Operations

```
int M.dim1()
```

returns n , the number of rows of M .

```
int M.dim2()
```

returns m , the number of columns of M .

```
integer_vector& M.row(int i)
```

returns the i -th row of M (an m - vector).
Precondition: $0 \leq i \leq n - 1$.

integer_vector $M.col(int\ i)$ returns the i -th column of M (an n - vector).
Precondition: $0 \leq i \leq m - 1$.

integer& $M(int\ i, int\ j)$ returns $M_{i,j}$.
Precondition: $0 \leq i \leq n - 1$ and $0 \leq j \leq m - 1$.

Arithmetic Operators

integer_matrix $M + const\ integer_matrix\&\ M1$
Addition.
Precondition:
 $M.dim1() == M1.dim1()$ and $M.dim2() == M1.dim2()$.

integer_matrix $M - const\ integer_matrix\&\ M1$
Subtraction.
Precondition:
 $M.dim1() == M1.dim1()$ and $M.dim2() == M1.dim2()$.

integer_matrix $M * const\ integer_matrix\&\ M1$
Multiplication.
Precondition:
 $M.dim2() == M1.dim1()$.

integer_vector $M * const\ integer_vector\&\ vec$
Multiplication with vector.
Precondition:
 $M.dim2() == vec.dim()$.

integer_matrix $const\ integer_matrix\&\ M * const\ integer\&\ x$
Multiplication of every entry with integer x .

integer_matrix $const\ integer\&\ x * const\ integer_matrix\&\ M$
Multiplication of every entry with integer x .

Non-Member Functions

integer_matrix $transpose(const\ integer_matrix\&\ M)$
returns M^T ($m \times n$ - matrix).

- integer_matrix* `inverse(const integer_matrix& M, integer& D)`
 returns the inverse matrix of M . More precisely, $1/D$ times the matrix returned is the inverse of M .
Precondition: $\text{determinant}(M) \neq 0$.
- bool* `inverse(const integer_matrix& M, integer_matrix& inverse, integer& D, integer_vector& c)`
 determines whether M has an inverse. It also computes either the inverse as $(1/D) \cdot \text{inverse}$ or a vector c such that $c^T \cdot M = 0$.
- integer* `determinant(const integer_matrix& M, integer_matrix& L, integer_matrix& U, array<int>& q, integer_vector& c)`
 returns the determinant D of M and sufficient information to verify that the value of the determinant is correct. If the determinant is zero then c is a vector such that $c^T \cdot M = 0$. If the determinant is non-zero then L and U are lower and upper diagonal matrices respectively and q encodes a permutation matrix Q with $Q(i, j) = 1$ iff $i = q(j)$ such that $L \cdot M \cdot Q = U$, $L(0, 0) = 1$, $L(i, i) = U(i - 1, i - 1)$ for all i , $1 \leq i < n$, and $D = s \cdot U(n - 1, n - 1)$ where s is the determinant of Q .
Precondition: M is quadratic.
- bool* `verify_determinant(const integer_matrix& M, integer D, integer_matrix& L, integer_matrix& U, array<int> q, integer_vector& c)`
 verifies the conditions stated above.
- integer* `determinant(const integer_matrix& M)`
 returns the determinant of M .
Precondition: M is quadratic.
- int* `sign_of_determinant(const integer_matrix& M)`
 returns the sign of the determinant of M .
Precondition: M is quadratic.
- bool* `linear_solver(const integer_matrix& M, const integer_vector& b, integer_vector& x, integer& D, integer_matrix& spanning_vectors, integer_vector& c)`
 determines the complete solution space of the linear system $M \cdot x = b$. If the system is unsolvable then $c^T \cdot M = 0$ and $c^T \cdot b \neq 0$. If the system is solvable then $(1/D)x$ is a solution, and the columns of *spanning_vectors* are a maximal set of linearly independent solutions to the corresponding homogeneous system.
Precondition: $M.\text{dim1}() == b.\text{dim}()$.

- bool* `linear_solver(const integer_matrix& M, const integer_vector& b,`
 `integer_vector& x, integer& D, integer_vector& c)`
 determines whether the linear system $M \cdot x = b$ is solvable. If yes, then $(1/D)x$ is a solution, if not then $c^T \cdot M = 0$ and $c^T \cdot b \neq 0$.
Precondition: $M.\text{dim1}() == b.\text{dim}()$.
- bool* `linear_solver(const integer_matrix& M, const integer_vector& b,`
 `integer_vector& x, integer& D)`
 as above, but without the witness c
Precondition: $M.\text{dim1}() == b.\text{dim}()$.
- bool* `is_solvable(const integer_matrix& M, const integer_vector& b)`
 determines whether the system $M \cdot x = b$ is solvable
Precondition: $M.\text{dim1}() == b.\text{dim}()$.
- bool* `homogeneous_linear_solver(const integer_matrix& M,`
 `integer_vector& x)`
 determines whether the homogeneous linear system $M \cdot x = 0$ has a non - trivial solution. If yes, then x is such a solution.
- int* `homogeneous_linear_solver(const integer_matrix& M,`
 `integer_matrix& spanning_vecs)`
 determines the solution space of the homogeneous linear system $M \cdot x = 0$. It returns the dimension of the solution space. Moreover the columns of *spanning_vecs* span the solution space.
- void* `independent_columns(const integer_matrix& M, array<int>& columns)`
 returns the indices of a maximal subset of independent columns of M . The index range of *columns* starts at 0.
- int* `rank(const integer_matrix& M)`
 returns the rank of matrix M
- ostream&* `ostream& O << const integer_matrix& M`
 writes matrix M row by row to the output stream O .
- istream&* `istream& I >> integer_matrix& M`
 reads matrix M row by row from the input stream I .

4. Implementation

The datatype *integer_matrix* is implemented by two-dimensional arrays of variables of type *integer*. Operations *determinant*, *inverse*, *linear_solver*, and *rank* take time $O(n^3)$, *column* takes time $O(n)$, *row*, *dim1*, *dim2*, take constant time, and all other operations take time $O(nm)$. The space requirement is $O(nm)$.

All functions on integer matrices compute the exact result, i.e., there is no rounding error. The implementation follows a proposal of J. Edmonds (J. Edmonds, Systems of

distinct representatives and linear algebra, Journal of Research of the Bureau of National Standards, (B), 71, 241 - 245). Most functions of linear algebra are *checkable*, i.e., the programs can be asked for a proof that their output is correct. For example, if the linear system solver declares a linear system $Ax = b$ unsolvable it also returns a vector c such that $c^T A = 0$ and $c^T b \neq 0$.

6.14 Rational Vectors (*rat_vector*)

1. Definition

An instance of data type *rat_vector* is a vector of rational numbers. A d -dimensional vector $r = (r_0, \dots, r_{d-1})$ is represented in homogeneous coordinates (h_0, \dots, h_d) , where $r_i = h_i/h_d$ and the h_i 's are of type *integer*. We call the r_i 's the cartesian coordinates of the vector. The homogenizing coordinate h_d is positive.

This data type is meant for use in computational geometry. It realizes free vectors as opposed to position vectors (type *rat_point*). The main difference between position vectors and free vectors is their behavior under affine transformations, e.g., free vectors are invariant under translations.

rat_vector is an item type.

```
#include < LEDA/numbers/rat_vector.h >
```

2. Creation

rat_vector $v(\text{int } d = 2)$; introduces a variable v of type *rat_vector* initialized to the zero vector of dimension d .

rat_vector $v(\text{integer } a, \text{integer } b, \text{integer } D)$;
introduces a variable v of type *rat_vector* initialized to the two-dimensional vector with homogeneous representation (a, b, D) if D is positive and representation $(-a, -b, -D)$ if D is negative.
Precondition: D is non-zero.

rat_vector $v(\text{rational } x, \text{rational } y)$;
introduces a variable v of type *rat_vector* initialized to the two-dimensional vector with homogeneous representation (a, b, D) , where $x = a/D$ and $y = b/D$.

rat_vector $v(\text{integer } a, \text{integer } b, \text{integer } c, \text{integer } D)$;
introduces a variable v of type *rat_vector* initialized to the three-dimensional vector with homogeneous representation (a, b, c, D) if D is positive and representation $(-a, -b, -c, -D)$ if D is negative.
Precondition: D is non-zero.

rat_vector $v(\text{rational } x, \text{rational } y, \text{rational } z)$;
introduces a variable v of type *rat_vector* initialized to the three-dimensional vector with homogeneous representation (a, b, c, D) , where $x = a/D$, $y = b/D$ and $z = c/D$.

rat_vector $v(\text{const array}\langle\text{rational}\rangle\& A);$

introduces a variable v of type *rat_vector* initialized to the d -dimensional vector with homogeneous coordinates $(\pm c_0, \dots, \pm c_{d-1}, \pm D)$, where $d = A.size()$ and $A[i] = c_i/D$, for $i = 0, \dots, d - 1$.

rat_vector $v(\text{integer } a, \text{integer } b);$

introduces a variable v of type *rat_vector* initialized to the two-dimensional vector with homogeneous representation $(a, b, 1)$.

rat_vector $v(\text{const integer_vector}\& c, \text{integer } D);$

introduces a variable v of type *rat_vector* initialized to the vector with homogeneous coordinates $(\pm c_0, \dots, \pm c_{d-1}, \pm D)$, where d is the dimension of c and the sign chosen is the sign of D .

Precondition: D is non-zero.

rat_vector $v(\text{const integer_vector}\& c);$

introduces a variable v of type *rat_vector* initialized to the direction with homogeneous coordinate vector $\pm c$, where the sign chosen is the sign of the last component of c .

Precondition: The last component of c is non-zero.

rat_vector $v(\text{const vector}\& w, \text{int } prec);$

introduces a variable v of type *rat_vector* initialized to $(\lfloor P * w_0 \rfloor, \dots, \lfloor P * w_{d-1} \rfloor, P)$, where d is the dimension of w and $P = 2^{prec}$.

3. Operations

3.1 Initialization, Access and Conversions

rat_vector $\text{rat_vector}::d2(\text{integer } a, \text{integer } b, \text{integer } D)$

returns a *rat_vector* of dimension 2 initialized to a vector with homogeneous representation (a, b, D) if D is positive and representation $(-a, -b, -D)$ if D is negative.

Precondition: D is non-zero.

<i>rat_vector</i>	<i>rat_vector</i> ::d3(<i>integer a</i> , <i>integer b</i> , <i>integer c</i> , <i>integer D</i>)	returns a <i>rat_vector</i> of dimension 3 initialized to a vector with homogeneous representation (<i>a</i> , <i>b</i> , <i>c</i> , <i>D</i>) if <i>D</i> is positive and representation (<i>-a</i> , <i>-b</i> , <i>-c</i> , <i>-D</i>) if <i>D</i> is negative. <i>Precondition</i> : <i>D</i> is non-zero.
<i>rat_vector</i>	<i>rat_vector</i> ::unit(<i>int i</i> , <i>int d = 2</i>)	returns a <i>rat_vector</i> of dimension <i>d</i> initialized to the <i>i</i> -th unit vector. <i>Precondition</i> : $0 \leq i < d$.
<i>rat_vector</i>	<i>rat_vector</i> ::zero(<i>int d = 2</i>)	returns the zero vector in <i>d</i> -dimensional space.
<i>int</i>	<i>v</i> .dim()	returns the dimension of <i>v</i> .
<i>integer</i>	<i>v</i> .hcoord(<i>int i</i>)	returns the <i>i</i> -th homogeneous coordinate of <i>v</i> .
<i>rational</i>	<i>v</i> .coord(<i>int i</i>)	returns the <i>i</i> -th cartesian coordinate of <i>v</i> .
<i>rational</i>	<i>v</i> [<i>int i</i>]	returns the <i>i</i> -th cartesian coordinate of <i>v</i> .
<i>rational</i>	<i>v</i> .sqr.length()	returns the square of the length of <i>v</i> .
<i>vector</i>	<i>v</i> .to_float()	returns a floating point approximation of <i>v</i> .

Additional Operations for vectors in two and three-dimensional space

<i>rational</i>	<i>v</i> .xcoord()	returns the zero-th cartesian coordinate of <i>v</i> .
<i>rational</i>	<i>v</i> .ycoord()	returns the first cartesian coordinate of <i>v</i> .
<i>rational</i>	<i>v</i> .zcoord()	returns the second cartesian coordinate of <i>v</i> .
<i>integer</i>	<i>v</i> .X()	returns the zero-th homogeneous coordinate of <i>v</i> .
<i>integer</i>	<i>v</i> .Y()	returns the first homogeneous coordinate of <i>v</i> .
<i>integer</i>	<i>v</i> .Z()	returns the second homogeneous coordinate of <i>v</i> .
<i>integer</i>	<i>v</i> .W()	returns the homogenizing coordinate of <i>v</i> .
<i>rat_vector</i>	<i>v</i> .rotate90(<i>int i = 1</i>)	returns <i>v</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise. <i>Precondition</i> : $v.dim() == 2$.

<i>int</i>	<code>compare_by_angle(const rat_vector& v1, const rat_vector& v2)</code>	For a non-zero vector v let $\alpha(v)$ be the angle by which the positive x -axis has to be turned counter-clockwise until it aligns with v . The function compares the angles defined by $v1$ and $v2$, respectively. The zero-vector precedes all non-zero vectors in the angle-order.
<i>rat_vector</i>	<code>cross_product(const rat_vector& v1, const rat_vector& v2)</code>	returns the cross product of the three-dimensional vectors $v1$ and $v2$.

3.2 Tests

<i>bool</i>	<code>v == const rat_vector& w</code>	Test for equality.
<i>bool</i>	<code>v != const rat_vector& w</code>	Test for inequality.

3.3 Arithmetical Operators

<i>rat_vector</i>	<code>integer n * const rat_vector& v</code>	multiplies all cartesian coordinates by n .
<i>rat_vector</i>	<code>rational r * const rat_vector& v</code>	multiplies all cartesian coordinates by r .
<i>rat_vector&</i>	<code>v *= integer n</code>	multiplies all cartesian coordinates by n .
<i>rat_vector&</i>	<code>v *= rational r</code>	multiplies all cartesian coordinates by r .
<i>rat_vector</i>	<code>const rat_vector& v / integer n</code>	divides all cartesian coordinates by n .
<i>rat_vector</i>	<code>const rat_vector& v / rational r</code>	divides all cartesian coordinates by r .
<i>rat_vector&</i>	<code>v /= integer n</code>	divides all cartesian coordinates by n .
<i>rat_vector&</i>	<code>v /= rational r</code>	divides all cartesian coordinates by r .
<i>rational</i>	<code>const v * const rat_vector& w</code>	scalar product, i.e., $\sum_{0 \leq i < d} v_i w_i$, where v_i and w_i are the cartesian coordinates of v and w respectively.
<i>rat_vector</i>	<code>const rat_vector& v + const rat_vector& w</code>	adds cartesian coordinates.

rat_vector& *v += const rat_vector& w* addition plus assignment.

rat_vector *const rat_vector& v - const rat_vector& w*
subtracts cartesian coordinates.

rat_vector& *v -= const rat_vector& w* subtraction plus assignment.

rat_vector *-v* returns *-v*.

3.4 Input and Output

ostream& *ostream& O << const rat_vector& v*
writes *v*'s homogeneous coordinates componentwise to the output stream *O*.

istream& *istream& I >> rat_vector& v*
reads *v*'s homogeneous coordinates componentwise from the input stream *I*. The operator uses the current dimension of *v*.

3.5 Linear Hull, Dependence and Rank

bool *contained_in_linear_hull(const array<rat_vector>& A, const rat_vector& x)*
determines whether *x* is contained in the linear hull of the vectors in *A*.

int *linear_rank(const array<rat_vector>& A)*
computes the linear rank of the vectors in *A*.

bool *linearly_independent(const array<rat_vector>& A)*
decides whether the vectors in *A* are linearly independent.

array<rat_vector> *linear_base(const array<rat_vector>& A)*
computes a basis of the linear space spanned by the vectors in *A*.

4. Implementation

Vectors are implemented by arrays of integers as an item type. All operations like creation, initialization, tests, vector arithmetic, input and output on an vector *v* take time $O(v.dim())$. *dim()*, coordinate access and conversions take constant time. The operations for linear hull, rank and independence have the cubic costs of the used matrix operations. The space requirement is $O(v.dim())$.

6.15 Real-Valued Vectors (`real_vector`)

1. Definition

An instance of data type `real_vector` is a vector of variables of type `real`.

```
#include < LEDA/numbers/real_vector.h >
```

2. Creation

`real_vector v;` creates an instance `v` of type `real_vector`; `v` is initialized to the zero-dimensional vector.

`real_vector v(int d);` creates an instance `v` of type `real_vector`; `v` is initialized to the zero vector of dimension `d`.

`real_vector v(real a, real b);`
creates an instance `v` of type `real_vector`; `v` is initialized to the two-dimensional vector (a, b) .

`real_vector v(real a, real b, real c);`
creates an instance `v` of type `real_vector`; `v` is initialized to the three-dimensional vector (a, b, c) .

`real_vector v(double a, double b);`
creates an instance `v` of type `real_vector`; `v` is initialized to the two-dimensional vector (a, b) .

`real_vector v(double a, double b, double c);`
creates an instance `v` of type `real_vector`; `v` is initialized to the three-dimensional vector (a, b, c) .

3. Operations

`int v.dim()` returns the dimension of `v`.

`real& v[int i]` returns `i`-th component of `v`.
Precondition: $0 \leq i \leq v.dim() - 1$.

`real v.hcoord(int i)` for compatibility with `rat_vector`.

`real v.coord(int i)` for compatibility with `rat_vector`.

`real v.sqr_length()` returns the square of the Euclidean length of `v`.

`real v.length()` returns the Euclidean length of `v`.

<i>real_vector</i> <i>v</i> .norm()	returns <i>v</i> normalized.
<i>real_vector</i> <i>v</i> .rotate90(<i>int</i> <i>i</i> = 1)	returns <i>v</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise. <i>Precondition</i> : $v.dim() = 2$
<i>real_vector</i> <i>v</i> + <i>const real_vector&</i> <i>v1</i>	Addition. <i>Precondition</i> : $v.dim() = v1.dim()$.
<i>real_vector</i> <i>v</i> - <i>const real_vector&</i> <i>v1</i>	Subtraction. <i>Precondition</i> : $v.dim() = v1.dim()$.
<i>real</i> <i>v</i> * <i>const real_vector&</i> <i>v1</i>	Scalar multiplication. <i>Precondition</i> : $v.dim() = v1.dim()$.
<i>real_vector&</i> <i>v</i> *= <i>real</i> <i>r</i>	multiplies all coordinates by <i>r</i> .
<i>real_vector</i> <i>v</i> * <i>real</i> <i>r</i>	Componentwise multiplication with real <i>r</i> .
<i>bool</i> <i>v</i> == <i>const real_vector&</i> <i>w</i>	Test for equality.
<i>bool</i> <i>v</i> != <i>const real_vector&</i> <i>w</i>	Test for inequality.
<i>void</i> <i>v</i> .print(<i>ostream&</i> <i>O</i>)	prints <i>v</i> componentwise to ostream <i>O</i> .
<i>void</i> <i>v</i> .print()	prints <i>v</i> to <i>cout</i> .
<i>void</i> <i>v</i> .read(<i>istream&</i> <i>I</i>)	reads $d = v.dim()$ numbers from input stream <i>I</i> and writes them into $v[0] \dots v[d - 1]$.
<i>void</i> <i>v</i> .read()	reads <i>v</i> from <i>cin</i> .
<i>ostream&</i> <i>ostream&</i> <i>O</i> << <i>const real_vector&</i> <i>v</i>	writes <i>v</i> componentwise to the output stream <i>O</i> .
<i>istream&</i> <i>istream&</i> <i>I</i> >> <i>real_vector&</i> <i>v</i>	reads <i>v</i> componentwise from the input stream <i>I</i> .
<i>vector</i> <i>v</i> .to_float()	returns a floating point approximation of <i>v</i> .

Additional Operations for vectors in two and three-dimensional space

<i>real</i> <i>v</i> .xcoord()	returns the zero-th cartesian coordinate of <i>v</i> .
<i>real</i> <i>v</i> .ycoord()	returns the first cartesian coordinate of <i>v</i> .
<i>real</i> <i>v</i> .zcoord()	returns the second cartesian coordinate of <i>v</i> .

int `compare_by_angle(const real_vector& v1, const real_vector& v2)`

For a non-zero vector v let $\alpha(v)$ be the angle by which the positive x -axis has to be turned counter-clockwise until it aligns with v . The function compares the angles defined by $v1$ and $v2$, respectively. The zero-vector precedes all non-zero vectors in the angle-order.

real_vector `cross_product(const real_vector& v1, const real_vector& v2)`

returns the cross product of the three-dimensional vectors $v1$ and $v2$.

4. Implementation

Vectors are implemented by arrays of real numbers. All operations on a vector v take $O(v.dim())$ real-number operations, except for `dim` and `[]` which take constant time. The space requirement depends on the size of the representations of the coordinates.

6.16 Real-Valued Matrices (`real_matrix`)

1. Definition

An instance of the data type `real_matrix` is a matrix of variables of type `real`.

```
#include < LEDA/numbers/real_matrix.h >
```

2. Creation

```
real_matrix  $M$ (int  $n = 0$ , int  $m = 0$ );
```

creates an instance M of type `real_matrix`, M is initialized to the $n \times m$ - zero matrix.

```
real_matrix  $M$ (int  $n$ , int  $m$ , real *  $D$ );
```

creates the $n \times m$ matrix M with $M(i, j) = D[i * m + j]$ for $0 \leq i \leq n - 1$ and $0 \leq j \leq m - 1$. *Precondition:* D points to an array of at least $n * m$ numbers of type `real`.

3. Operations

```
int  $M$ .dim1() returns  $n$ , the number of rows of  $M$ .
```

```
int  $M$ .dim2() returns  $m$ , the number of columns of  $M$ .
```

```
real_vector&  $M$ .row(int  $i$ ) returns the  $i$ -th row of  $M$  (an  $m$ -vector).  
Precondition:  $0 \leq i \leq n - 1$ .
```

```
real_vector  $M$ .col(int  $i$ ) returns the  $i$ -th column of  $M$  (an  $n$ -vector).  
Precondition:  $0 \leq i \leq m - 1$ .
```

```
real_matrix  $M$ .trans() returns  $M^T$  ( $m \times n$  - matrix).
```

```
real_matrix  $M$ .inv() returns the inverse matrix of  $M$ .  
Precondition:  $M$  is quadratic and  $M$ .det()  $\neq 0$ .
```

```
real  $M$ .det() returns the determinant of  $M$ .  
Precondition:  $M$  is quadratic.
```

```
real_vector  $M$ .solve(const real_vector&  $b$ )  
returns vector  $x$  with  $M \cdot x = b$ .  
Precondition:  $M$ .dim1() ==  $M$ .dim2() ==  $b$ .dim() and  $M$ .det()  $\neq 0$ .
```

```
real&  $M$ (int  $i$ , int  $j$ ) returns  $M_{i,j}$ .  
Precondition:  $0 \leq i \leq n - 1$  and  $0 \leq j \leq m - 1$ .
```

real_matrix $M + \text{const } \text{real_matrix\&} M1$

Addition.

Precondition: $M.\text{dim1}() == M1.\text{dim1}()$ and $M.\text{dim2}() == M1.\text{dim2}()$.

real_matrix $M - \text{const } \text{real_matrix\&} M1$

Subtraction.

Precondition: $M.\text{dim1}() == M1.\text{dim1}()$ and $M.\text{dim2}() == M1.\text{dim2}()$.

real_matrix $M * \text{const } \text{real_matrix\&} M1$

Multiplication.

Precondition: $M.\text{dim2}() == M1.\text{dim1}()$.

real_vector $M * \text{const } \text{real_vector\&} \text{vec}$

Multiplication with vector.

Precondition: $M.\text{dim2}() == \text{vec}.\text{dim}()$.

real_matrix $M * \text{real } x$

Multiplication with real x .

void $M.\text{print}(\text{ostream\&} O)$

prints M row by row to ostream O .

void $M.\text{print}()$

prints M cout.

void $M.\text{read}(\text{istream\&} I)$ reads $M.\text{dim1}()$ \times $M.\text{dim2}()$ numbers from input stream I and writes them row by row into matrix M .

void $M.\text{read}()$

prints M from cin.

ostream\& $\text{ostream\&} O \ll \text{const } \text{real_matrix\&} M$

writes matrix M row by row to the output stream O .

istream\& $\text{istream\&} I \gg \text{real_matrix\&} M$

reads a matrix row by row from the input stream I and assigns it to M .

4. Implementation

Data type *real_matrix* is implemented by two-dimensional arrays of real numbers. Operations *det*, *solve*, and *inv* take time $O(n^3)$ operations on reals, *dim1*, *dim2*, *row*, and *col* take constant time, all other operations perform $O(nm)$ operations on reals. The space requirement is $O(nm)$ plus the space for the nm entries of type *real*.

6.17 Numerical Analysis Functions (numerical_analysis)

We collect some functions of numerical analysis. *The algorithms in this section are not the best known and are not recommended for serious use.* We refer the reader to the book “Numerical Recipes in C: The Art of Scientific Computing” by B.P. Flannery, W.H. Press, S.A. Teukolsky, and W.T. Vetterling, Cambridge University Press for better algorithms.

The functions in this section become available by including *numerical_analysis.h*.

6.17.1 Minima and Maxima

double minimize_function(*double* (**f*)(*double*), *double*& *xmin*, *double* *tol* = 1.0e - 10)

finds a local minimum of the function *f* of one argument. The minimizing argument is returned in *xmin* and the minimal function value is returned as the result of the function. *xmin* is determined with tolerance *tol*, i.e., the true value of the minimizing argument is contained in the interval $[xmin(1 - \epsilon), xmin(1 + \epsilon)]$, where $\epsilon = \max(1, xmin) \cdot tol$. Please do not choose *tol* smaller than 10^{-15} .

Precondition: : If $+\infty$ or $-\infty$ is a local minimum of *f*, then the call of *minimize_function* may not terminate.

The algorithm is implemented as follows: First three arguments are determined such that $a < b < c$ (or $a > b > c$) and $f(a) \geq f(b) \leq f(c)$, i.e., *a* and *c* bracket a minimum. The interval is found by first taking two arbitrary arguments and comparing their function values. The argument with the larger function value is taken as *a*. Then steps of larger and larger size starting at *b* are taken until a function value larger than $f(b)$ is found. Once the bracketing interval is found, golden-ratio search is applied to it.

template <class *F*>

double minimize_function(const *F*& *f*, *double*& *xmin*, *double* *tol* = 1.0e - 10)

a more flexible version of the above. It is assumed that class *F* offers the operator *double operator*()(*double* *x*). This operator is taken as the function *f*.

6.17.2 Integration

double integrate_function(*double* (*f)(*double*), *double* l, *double* r,
double delta = 1.0e - 2)

Computes the integral of f in the interval $[l, r]$ by forming the sum $\text{delta} * \sum_{0 \leq i < K} f(l + i \cdot \text{delta})$, where $K = (r - l) / \text{delta}$.
Precondition: $l \leq r$ and $\text{delta} > 0$.

template <class F>

double integrate_function(const F& f, *double* l, *double* r, *double* delta = 1.0e - 2)

a more flexible version of the above. It is assumed that class F offers the operator $\text{double operator}(\text{ })(\text{double } x)$. This operator is taken as the function f .

6.17.3 Useful Numerical Functions

double binary_entropy(*double* x)

returns the binary entropy of x , i.e., $-x \cdot \log x - (1 - x) \cdot \log(1 - x)$.

Precondition: $0 \leq x \leq 1$.

6.17.4 Root Finding

double zero_of_function(*double* (*f)(*double*), *double* l, *double* r, *double* tol = 1.0e - 10)

returns a zero x of f . We have either $|f(x)| \leq 10^{-10}$ or there is an interval $[x_0, x_1]$ containing x such that $f(x_0) \cdot f(x_1) \leq 0$ and $x_1 - x_0 \leq \text{tol} \cdot \max(1, |x_1| + |x_0|)$.

Precondition: $l \leq r$ and $f(l) \cdot f(r) \leq 0$.

template <class F>

double zero_of_function(const F& f, *double* l, *double* r, *double* tol = 1.0e - 10)

a more flexible version of the above. It is assumed that class F offers the operator $\text{double operator}(\text{ })(\text{double } x)$. This operator is taken as the function f .

Chapter 7

Basic Data Types

7.1 One Dimensional Arrays (`array`)

1. Definition

An instance A of the parameterized data type `array<E>` is a mapping from an interval $I = [a..b]$ of integers, the index set of A , to the set of variables of data type E , the element type of A . $A(i)$ is called the element at position i . The array access operator ($A[i]$) checks its precondition ($a \leq i \leq b$). The check can be turned off by compiling with the flag `-DLEDA_CHECKING_OFF`.

```
#include < LEDA/core/array.h >
```

2. Types

`array<E>::item` the item type.

`array<E>::value_type` the value type.

3. Creation

`array<E> A(int low, int high);`
 creates an instance A of type `array<E>` with index set $[low..high]$.

`array<E> A(int n);`
 creates an instance A of type `array<E>` with index set $[0..n - 1]$.

`array<E> A;` creates an instance A of type `array<E>` with empty index set.

Special Constructors

`array<E> A(int low, const E& x, const E& y);`
 creates an instance A of type `array<E>` with index set $[low, low + 1]$ initialized to $[x, y]$.

array<E> *A*(*int low*, *const E& x*, *const E& y*, *const E& w*);
 creates an instance *A* of type *array<E>* with index set [*low*, *low* + 2]
 initialized to [*x*, *y*, *w*].

array<E> *A*(*int low*, *const E& x*, *const E& y*, *const E& z*, *const E& w*);
 creates an instance *A* of type *array<E>* with index set [*low*, *low* + 3]
 initialized to [*x*, *y*, *z*, *w*].

4. Operations

Basic Operations

E& *A*[*int x*] returns *A*(*x*).
Precondition: $a \leq x \leq b$.

E& *A*.get(*int x*) returns *A*(*x*).
Precondition: $a \leq x \leq b$.

void *A*.set(*int x*, *const E& e*) sets *A*(*x*) = *e*.
Precondition: $a \leq x \leq b$.

void *A*.swap(*int i*, *int j*) swaps the values of *A*[*i*] and *A*[*j*].

void *A*.copy(*int x*, *int y*) sets *A*(*x*) = *A*(*y*).
Precondition: $a \leq x \leq b$ and $low() \leq y \leq high()$.

void *A*.copy(*int x*, *const array<E>& B*, *int y*)
 sets *A*(*x*) = *B*(*y*).
Precondition: $a \leq x \leq b$ and $B.low() \leq y \leq B.high()$.

void *A*.resize(*int low*, *int high*) sets the index set of *A* to [*a*..*b*] such that for all *i* ∈ [*a*..*b*]
 which are not contained in the old index set *A*(*i*) is set
 to the default value of type *E*.

void *A*.resize(*int n*) same as *A*.resize(0, *n* - 1).

int *A*.low() returns the minimal index *a* of *A*.

int *A*.high() returns the maximal index *b* of *A*.

int *A*.size() returns the size (*b* - *a* + 1) of *A*.

void *A*.init(*const E& x*) assigns *x* to *A*[*i*] for every *i* ∈ { *a* ... *b* }.

bool *A*.C_style() returns *true* if the array has “C-style”, i.e., the index
 set is [*0*..*size* - 1].

void A.permute() the elements of *A* are randomly permuted.

void A.permute(*int low*, *int high*)
the elements of *A[low..high]* are randomly permuted.

Sorting and Searching

void A.sort(*int (*cmp)*(*const E&* , *const E&*))
sorts the elements of *A*, using function *cmp* to compare two elements, i.e., if (in_a, \dots, in_b) and (out_a, \dots, out_b) denote the values of the variables $(A(a), \dots, A(b))$ before and after the call of *sort*, then $cmp(out_i, out_j) \leq 0$ for $i \leq j$ and there is a permutation π of $[a..b]$ such that $out_i = in_{\pi(i)}$ for $a \leq i \leq b$.

void A.sort()
sorts the elements of *A* according to the linear order of the element type *E*. *Precondition*: A linear order on *E* must have been defined by *compare(const E&, const E&)* if *E* is a user-defined type (see Section 2.3)..

void A.sort(*int (*cmp)*(*const E&* , *const E&*), *int low*, *int high*)
sorts sub-array *A[low..high]* using compare function *cmp*.

void A.sort(*int low*, *int high*)
sorts sub-array *A[low..high]* using the linear order on *E*. If *E* is a user-defined type, you have to define the linear order by providing the compare function (see Section 2.3).

int A.unique()
removes duplicates from *A* by copying the unique elements of *A* to *A[A.low()]*, ..., *A[h]* and returns *h* (*A.low()* - 1 if *A* is empty). *Precondition*: *A* is sorted increasingly according to the default ordering of type *E*. If *E* is a user-defined type, you have to define the linear order by providing the compare function (see Section 2.3).

int A.binary_search(*int (*cmp)*(*const E&* , *const E&*), *const E&* *x*)
performs a binary search for *x*. Returns an *i* with $A[i] = x$ if *x* in *A*, *A.low()* - 1 otherwise. Function *cmp* is used to compare two elements.
Precondition: *A* must be sorted according to *cmp*.

int A.binary_search(*const E&* *x*)
as above but uses the default linear order on *E*. If *E* is a user-defined type, you have to define the linear order by providing the compare function (see Section 2.3).

int `A.binary_locate(int (*cmp)(const E&, const E&), const E& x)`
 Returns the maximal i with $A[i] \leq x$ or $A.lower() - 1$ if $x < A.lower()$. Function *cmp* is used to compare elements.
Precondition: *A* must be sorted according to *cmp*.

int `A.binary_locate(const E& x)`
 as above but uses the default linear order on *E*. If *E* is a user-defined type, you have to define the linear order by providing the compare function (see Section 2.3).

Input and Output

void `A.read(istream& I)` reads $b - a + 1$ objects of type *E* from the input stream *I* into the array *A* using the operator \gg (*istream&, E&*).

void `A.read()` calls `A.read(cin)` to read *A* from the standard input stream *cin*.

void `A.read(string s)` As above, uses string *s* as prompt.

void `A.print(ostream& O, char space = '')`
 prints the contents of array *A* to the output stream *O* using operator \ll (*ostream&, const E&*) to print each element. The elements are separated by character *space*.

void `A.print(char space = '')` calls `A.print(cout, space)` to print *A* on the standard output stream *cout*.

void `A.print(string s, char space = '')`
 As above, uses string *s* as header.

ostream& ostream& out \ll `const array<E>& A`
 same as `A.print(out)`; returns *out*.

istream& istream& in \gg `array<E>& A`
 same as `A.read(in)`; returns *in*.

Iteration

STL compatible iterators are provided when compiled with `-DLEDA_STL_ITERATORS` (see `LEDAROOT/demo/stl/array.c` for an example).

5. Implementation

Arrays are implemented by C++ vectors. The access operation takes time $O(1)$, the sorting is realized by quicksort (time $O(n \log n)$) and the `binary_search` operation takes time $O(\log n)$, where $n = b - a + 1$. The space requirement is $O(n * \text{sizeof}(E))$.

7.2 Two Dimensional Arrays (array2)

1. Definition

An instance A of the parameterized data type $array2\langle E \rangle$ is a mapping from a set of pairs $I = [a..b] \times [c..d]$, called the index set of A , to the set of variables of data type E , called the element type of A , for two fixed intervals of integers $[a..b]$ and $[c..d]$. $A(i, j)$ is called the element at position (i, j) .

```
#include < LEDA/core/array2.h >
```

2. Creation

```
array2<E> A(int a, int b, int c, int d);
```

creates an instance A of type $array2\langle E \rangle$ with index set $[a..b] \times [c..d]$.

```
array2<E> A(int n, int m);
```

creates an instance A of type $array2\langle E \rangle$ with index set $[0..n-1] \times [0..m-1]$.

3. Operations

```
void A.init(const E& x) assigns  $x$  to each element of  $A$ .
```

```
E& A(int i, int j) returns  $A(i, j)$ .  
Precondition:  $a \leq i \leq b$  and  $c \leq j \leq d$ .
```

```
int A.low1() returns  $a$ .
```

```
int A.high1() returns  $b$ .
```

```
int A.low2() returns  $c$ .
```

```
int A.high2() returns  $d$ .
```

4. Implementation

Two dimensional arrays are implemented by C++vectors. All operations take time $O(1)$, the space requirement is $O(I * sizeof(E))$.

7.3 Stacks (stack)

1. Definition

An instance S of the parameterized data type $stack\langle E \rangle$ is a sequence of elements of data type E , called the element type of S . Insertions or deletions of elements take place only at one end of the sequence, called the top of S . The size of S is the length of the sequence, a stack of size zero is called the empty stack.

```
#include < LEDA/core/stack.h >
```

2. Creation

$stack\langle E \rangle S$; creates an instance S of type $stack\langle E \rangle$. S is initialized with the empty stack.

3. Operations

$const E\&$	$S.top()$	returns the top element of S . <i>Precondition:</i> S is not empty.
$void$	$S.push(const E\& x)$	adds x as new top element to S .
E	$S.pop()$	deletes and returns the top element of S . <i>Precondition:</i> S is not empty.
int	$S.size()$	returns the size of S .
$bool$	$S.empty()$	returns true if S is empty, false otherwise.
$void$	$S.clear()$	makes S the empty stack.

4. Implementation

Stacks are implemented by singly linked linear lists. All operations take time $O(1)$, except clear which takes time $O(n)$, where n is the size of the stack.

7.4 Queues (queue)

1. Definition

An instance Q of the parameterized data type $queue<E>$ is a sequence of elements of data type E , called the element type of Q . Elements are inserted at one end (the rear) and deleted at the other end (the front) of Q . The size of Q is the length of the sequence; a queue of size zero is called the empty queue.

```
#include < LEDA/core/queue.h >
```

2. Types

$queue<E>::value_type$ the value type.

3. Creation

$queue<E> Q;$ creates an instance Q of type $queue<E>$. Q is initialized with the empty queue.

4. Operations

$const E\& Q.top()$ returns the front element of Q .
Precondition: Q is not empty.

$E Q.pop()$ deletes and returns the front element of Q .
Precondition: Q is not empty.

$void Q.append(const E\& x)$ appends x to the rear end of Q .

$void Q.push(const E\& x)$ inserts x at the front end of Q .

$int Q.size()$ returns the size of Q .

$int Q.length()$ returns the size of Q .

$bool Q.empty()$ returns true if Q is empty, false otherwise.

$void Q.clear()$ makes Q the empty queue.

Iteration

forall(x, Q) { “the elements of Q are successively assigned to x ” }

5. Implementation

Queues are implemented by singly linked linear lists. All operations take time $O(1)$, except clear which takes time $O(n)$, where n is the size of the queue.

7.5 Bounded Stacks (`b_stack`)

1. Definition

An instance S of the parameterized data type `b_stack<E>` is a stack (see section 7.3) of bounded size.

```
#include < LEDA/core/b_stack.h >
```

2. Creation

```
b_stack<E> S(int n);
```

creates an instance S of type `b_stack<E>` that can hold up to n elements. S is initialized with the empty stack.

3. Operations

<code>const E& S.top()</code>	returns the top element of S . <i>Precondition:</i> S is not empty.
<code>const E& S.pop()</code>	deletes and returns the top element of S . <i>Precondition:</i> S is not empty.
<code>void S.push(const E& x)</code>	adds x as new top element to S . <i>Precondition:</i> $S.size() < n$.
<code>void S.clear()</code>	makes S the empty stack.
<code>int S.size()</code>	returns the size of S .
<code>bool S.empty()</code>	returns true if S is empty, false otherwise.

4. Implementation

Bounded stacks are implemented by C++vectors. All operations take time $O(1)$. The space requirement is $O(n)$.

7.6 Bounded Queues (b_queue)

1. Definition

An instance Q of the parameterized data type $b_queue<E>$ is a (double ended) queue (see section 7.4) of bounded size.

```
#include < LEDA/core/b_queue.h >
```

2. Creation

```
b_queue<E> Q(int n);
```

creates an instance Q of type $b_queue<E>$ that can hold up to n elements. Q is initialized with the empty queue.

3. Operations

<i>const E&</i> $Q.front()$	returns the first element of Q . <i>Precondition:</i> Q is not empty.
<i>const E&</i> $Q.back()$	returns the last element of Q . <i>Precondition:</i> Q is not empty.
<i>const E&</i> $Q.pop_front()$	deletes and returns the first element of Q . <i>Precondition:</i> Q is not empty.
<i>const E&</i> $Q.pop_back()$	deletes and returns the last element of Q . <i>Precondition:</i> Q is not empty.
<i>void</i> $Q.push_front(const E& x)$	inserts x at the beginning of Q . <i>Precondition:</i> $Q.size() < n$.
<i>void</i> $Q.push_back(const E& x)$	inserts x at the end of Q . <i>Precondition:</i> $Q.size() < n$.
<i>void</i> $Q.append(const E& x)$	same as $Q.push_back()$.
<i>void</i> $Q.clear()$	makes Q the empty queue.
<i>int</i> $Q.size()$	returns the size of Q .
<i>int</i> $Q.length()$	same as $Q.size()$.
<i>bool</i> $Q.empty()$	returns true if Q is empty, false otherwise.

Stack Operations

const E& $Q.top()$ same as $Q.front()$.

7.7 Linear Lists (list)

1. Definition

An instance L of the parameterized data type $list\langle E \rangle$ is a sequence of items ($list\langle E \rangle :: item$). Each item in L contains an element of data type E , called the element or value type of L . The number of items in L is called the length of L . If L has length zero it is called the empty list. In the sequel $\langle x \rangle$ is used to denote a list item containing the element x and $L[i]$ is used to denote the contents of list item i in L .

```
#include < LEDA/core/list.h >
```

2. Types

$list\langle E \rangle :: item$ the item type.

$list\langle E \rangle :: value_type$ the value type.

3. Creation

$list\langle E \rangle L;$ creates an instance L of type $list\langle E \rangle$ and initializes it to the empty list.

4. Operations

Access Operations

int $L.length()$ returns the length of L .

int $L.size()$ returns $L.length()$.

$bool$ $L.empty()$ returns true if L is empty, false otherwise.

$list_item$ $L.first()$ returns the first item of L (nil if L is empty).

$list_item$ $L.last()$ returns the last item of L . (nil if L is empty)

$list_item$ $L.get_item(int\ i)$ returns the item at position i (the first position is 0).
Precondition: $0 \leq i < L.length()$. **Note** that this takes time linear in i .

$list_item$ $L.succ(list_item\ it)$ returns the successor item of item it , nil if $it = L.last()$.
Precondition: it is an item in L .

$list_item$ $L.pred(list_item\ it)$ returns the predecessor item of item it , nil if $it = L.first()$.
Precondition: it is an item in L .

<i>list_item</i>	<i>L.cyclic_succ(list_item it)</i>	returns the cyclic successor of item <i>it</i> , i.e., <i>L.first()</i> if <i>it = L.last()</i> , <i>L.succ(it)</i> otherwise.
<i>list_item</i>	<i>L.cyclic_pred(list_item it)</i>	returns the cyclic predecessor of item <i>it</i> , i.e., <i>L.last()</i> if <i>it = L.first()</i> , <i>L.pred(it)</i> otherwise.
<i>const E&</i>	<i>L.contents(list_item it)</i>	returns the contents <i>L[it]</i> of item <i>it</i> . <i>Precondition: it is an item in L.</i>
<i>const E&</i>	<i>L.inf(list_item it)</i>	returns <i>L.contents(it)</i> .
<i>const E&</i>	<i>L.front()</i>	returns the first element of <i>L</i> , i.e. the contents of <i>L.first()</i> . <i>Precondition: L is not empty.</i>
<i>const E&</i>	<i>L.head()</i>	same as <i>L.front()</i> .
<i>const E&</i>	<i>L.back()</i>	returns the last element of <i>L</i> , i.e. the contents of <i>L.last()</i> . <i>Precondition: L is not empty.</i>
<i>const E&</i>	<i>L.tail()</i>	same as <i>L.back()</i> .
<i>int</i>	<i>L.rank(const E& x)</i>	returns the rank of <i>x</i> in <i>L</i> , i.e. its first position in <i>L</i> as an integer from $[1.. L]$ (0 if <i>x</i> is not in <i>L</i>). Note that this takes time linear in <i>rank(x)</i> . <i>Precondition: operator== has to be defined for type E.</i>

Update Operations

<i>list_item</i>	<i>L.push(const E& x)</i>	adds a new item $\langle x \rangle$ at the front of <i>L</i> and returns it (<i>L.insert(x, L.first(), leda::before)</i>).
<i>list_item</i>	<i>L.push_front(const E& x)</i>	same as <i>L.push(x)</i> .
<i>list_item</i>	<i>L.append(const E& x)</i>	appends a new item $\langle x \rangle$ to <i>L</i> and returns it (<i>L.insert(x, L.last(), leda::behind)</i>).
<i>list_item</i>	<i>L.push_back(const E& x)</i>	same as <i>L.append(x)</i> .
<i>list_item</i>	<i>L.insert(const E& x, list_item pos, int dir = leda::behind)</i>	inserts a new item $\langle x \rangle$ behind (if <i>dir = leda::behind</i>) or in front of (if <i>dir = leda::before</i>) item <i>pos</i> into <i>L</i> and returns it (here <i>leda::behind</i> and <i>leda::before</i> are predefined constants). <i>Precondition: it is an item in L.</i>
<i>E</i>	<i>L.pop()</i>	deletes the first item from <i>L</i> and returns its contents. <i>Precondition: L is not empty.</i>

<i>E</i>	<code>L.pop_front()</code>	same as <code>L.pop()</code> .
<i>E</i>	<code>L.pop_back()</code>	deletes the last item from <i>L</i> and returns its contents. <i>Precondition:</i> <i>L</i> is not empty.
<i>E</i>	<code>L.Pop()</code>	same as <code>L.pop_back()</code> .
<i>E</i>	<code>L.delItem(list_item it)</code>	deletes the item <i>it</i> from <i>L</i> and returns its contents <code>L[it]</code> . <i>Precondition:</i> <i>it</i> is an item in <i>L</i> .
<i>E</i>	<code>L.del(list_item it)</code>	same as <code>L.delItem(it)</code> .
<i>void</i>	<code>L.erase(list_item it)</code>	deletes the item <i>it</i> from <i>L</i> . <i>Precondition:</i> <i>it</i> is an item in <i>L</i> .
<i>void</i>	<code>L.remove(const E& x)</code>	removes all items with contents <i>x</i> from <i>L</i> . <i>Precondition:</i> <code>operator==</code> has to be defined for type <i>E</i> .
<i>void</i>	<code>L.move_to_front(list_item it)</code>	moves <i>it</i> to the front end of <i>L</i> .
<i>void</i>	<code>L.move_to_rear(list_item it)</code>	moves <i>it</i> to the rear end of <i>L</i> .
<i>void</i>	<code>L.move_to_back(list_item it)</code>	same as <code>L.move_to_rear(it)</code> .
<i>void</i>	<code>L.assign(list_item it, const E& x)</code>	makes <i>x</i> the contents of item <i>it</i> . <i>Precondition:</i> <i>it</i> is an item in <i>L</i> .
<i>void</i>	<code>L.conc(list<E>& L1, int dir = leda::behind)</code>	appends (<i>dir</i> = <code>leda::behind</code> or prepends (<i>dir</i> = <code>leda::before</code>) list <i>L</i> ₁ to list <i>L</i> and makes <i>L</i> ₁ the empty list. <i>Precondition:</i> $L \neq L_1$
<i>void</i>	<code>L.swap(list<E>& L1)</code>	swaps lists of items of <i>L</i> and <i>L</i> ₁ ;
<i>void</i>	<code>L.split(list_item it, list<E>& L1, list<E>& L2)</code>	splits <i>L</i> at item <i>it</i> into lists <i>L</i> ₁ and <i>L</i> ₂ . More precisely, if <i>it</i> \neq <i>nil</i> and $L = x_1, \dots, x_{k-1}, it, x_{k+1}, \dots, x_n$ then $L_1 = x_1, \dots, x_{k-1}$ and $L_2 = it, x_{k+1}, \dots, x_n$. If <i>it</i> = <i>nil</i> then <i>L</i> ₁ is made empty and <i>L</i> ₂ a copy of <i>L</i> . Finally <i>L</i> is made empty if it is not identical to <i>L</i> ₁ or <i>L</i> ₂ . <i>Precondition:</i> <i>it</i> is an item of <i>L</i> or <i>nil</i> .

Sorting and Searching

void *L.sort(int (*cmp)(const E& , const E&))*
 sorts the items of *L* using the ordering defined by the compare function $cmp : E \times E \rightarrow int$, with

$$cmp(a, b) \begin{cases} < 0, & \text{if } a < b \\ = 0, & \text{if } a = b \\ > 0, & \text{if } a > b \end{cases}$$

More precisely, if (in_1, \dots, in_n) and (out_1, \dots, out_n) denote the values of *L* before and after the call of *sort*, then $cmp(L[out_j], L[out_{j+1}]) \leq 0$ for $1 \leq j < n$ and there is a permutation π of $[1..n]$ such that $out_i = in_{\pi_i}$ for $1 \leq i \leq n$.

void *L.sort()*
 sorts the items of *L* using the default ordering of type *E*, i.e., the linear order defined by function *int compare(const E&, const E&)*. If *E* is a user-defined type, you have to provide the compare function (see Section 2.3).

void *L.merge_sort(int (*cmp)(const E& , const E&))*
 sorts the items of *L* using merge sort and the ordering defined by *cmp*. The sort is stable, i.e., if $x = y$ and $\langle x \rangle$ is before $\langle y \rangle$ in *L* then $\langle x \rangle$ is before $\langle y \rangle$ after the sort. *L.merge_sort()* is more efficient than *L.sort()* if *L* contains large pre-sorted intervals.

void *L.merge_sort()*
 as above, but uses the default ordering of type *E*. If *E* is a user-defined type, you have to provide the compare function (see Section 2.3).

void *L.bucket_sort(int i, int j, int (*b)(const E&))*
 sorts the items of *L* using bucket sort, where *b* maps every element *x* of *L* to a bucket $b(x) \in [i..j]$. If $b(x) < b(y)$ then $\langle x \rangle$ appears before $\langle y \rangle$ after the sort. If $b(x) = b(y)$, the relative order of *x* and *y* before the sort is retained, thus the sort is stable.

void *L.bucket_sort(int (*b)(const E&))*
 sorts *list<E>* into increasing order as prescribed by *b* *Precondition*: *b* is an integer-valued function on *E*.

- () merges the items of L and $L1$ using the ordering defined by cmp . The result is assigned to L and $L1$ is made empty.
Precondition: L and $L1$ are sorted increasingly according to the linear order defined by cmp .
- void* $L.merge(list<E>\& L1)$ merges the items of L and $L1$ using the default linear order of type E . If E is a user-defined type, you have to define the linear order by providing the compare function (see Section 2.3).
- void* $L.unique(int (*cmp)(const E\& , const E\&))$
removes duplicates from L .
Precondition: L is sorted increasingly according to the ordering defined by cmp .
- void* $L.unique()$
removes duplicates from L .
Precondition: L is sorted increasingly according to the default ordering of type E and `operator==` is defined for E . If E is a user-defined type, you have to define the linear order by providing the compare function (see Section 2.3).
- list_item* $L.search(const E\& x)$ returns the first item of L that contains x , nil if x is not an element of L .
Precondition: `operator==` has to be defined for type E .
- list_item* $L.min(const leda_cmp_base<E>\& cmp)$
returns the item with the minimal contents with respect to the linear order defined by compare function cmp .
- list_item* $L.min()$ returns the item with the minimal contents with respect to the default linear order of type E .
- list_item* $L.max(const leda_cmp_base<E>\& cmp)$
returns the item with the maximal contents with respect to the linear order defined by compare function cmp .
- list_item* $L.max()$ returns the item with the maximal contents with respect to the default linear order of type E .

Input and Output

- void* $L.read(istream\& I)$ reads a sequence of objects of type E from the input stream I using `operator >>` ($istream\&, E\&$). L is made a list of appropriate length and the sequence is stored in L .

- void* *L.read(istream& I, char delim)*
as above but stops reading as soon as the first occurrence of character *delim* is encountered.
- void* *L.read(char delim = '\n')*
calls *L.read(cin, delim)* to read *L* from the standard input stream *cin*.
- void* *L.read(string prompt, char delim = '\n')*
As above, but first writes string *prompt* to *cout*.
- void* *L.print(ostream& O, char space = '')*
prints the contents of list *L* to the output stream *O* using operator \ll (*ostream&, const E&*) to print each element. The elements are separated by character *space*.
- void* *L.print(char space = '')* calls *L.print(cout, space)* to print *L* on the standard output stream *cout*.
- void* *L.print(string header, char space = '')*
As above, but first outputs string *header*.

Operators

- list<E>& L = const list<E>& L1* The assignment operator makes *L* a copy of list *L₁*. More precisely if *L₁* is the sequence of items *x₁, x₂, ..., x_n* then *L* is made a sequence of items *y₁, y₂, ..., y_n* with *L[y_i] = L₁[x_i]* for $1 \leq i \leq n$.
- E& L[list_item it]* returns a reference to the contents of *it*.
- list_item L[int i]* an abbreviation for *L.get_item(i)*.
- list_item L += const E& x* same as *L.append(x)*; returns the new item.
- ostream& ostream& out << const list<E>& L*
same as *L.print(out)*; returns *out*.
- istream& istream& in >> list<E>& L*
same as *L.read(in)*; returns *in*.

Iteration

forall_items(*it, L*) { “the items of *L* are successively assigned to *it*” }

forall(*x, L*) { “the elements of *L* are successively assigned to *x*” }

STL compatible iterators are provided when compiled with `-DLEDA_STL_ITERATORS` (see `LEDAROOT/demo/stl/list.c` for an example).

5. Implementation

The data type list is realized by doubly linked linear lists. Let c be the time complexity of the compare function and let d be the time needed to copy an object of type $list<E>$. All operations take constant time except of the following operations: search, `revers_items`, `permute` and `rank` take linear time $O(n)$, `item(i)` takes time $O(i)$, `min`, `max`, and `unique` take time $O(c \cdot n)$, `merge` takes time $O(c \cdot (n_1 + n_2))$, `operator=`, `apply`, `reverse`, `read`, and `print` take time $O(d \cdot n)$, `sort` and `merge_sort` take time $O(n \cdot c \cdot \log n)$, and `bucket_sort` takes time $O(e \cdot n + j - i)$, where e is the time complexity of f . n is always the current length of the list.

7.8 Singly Linked Lists (slist)

1. Definition

An instance L of the parameterized data type $slist<E>$ is a sequence of items ($slist<E>::item$). Each item in L contains an element of data type E , called the element or value type of L . The number of items in L is called the length of L . If L has length zero it is called the empty list. In the sequel $\langle x \rangle$ is used to denote a list item containing the element x and $L[i]$ is used to denote the contents of list item i in L .

```
#include < LEDA/core/slist.h >
```

2. Types

$slist<E>::item$ the item type.

$slist<E>::value_type$ the value type.

3. Creation

$slist<E> L;$ creates an instance L of type $slist<E>$ and initializes it to the empty list.

$slist<E> L(const E\& x);$ creates an instance L of type $slist<E>$ and initializes it to the one-element list $\langle x \rangle$.

4. Operations

int $L.length()$ returns the length of L .

int $L.size()$ returns $L.length()$.

$bool$ $L.empty()$ returns true if L is empty, false otherwise.

$item$ $L.first()$ returns the first item of L .

$item$ $L.last()$ returns the last item of L .

$item$ $L.succ(item\ it)$ returns the successor item of item it , nil if $it = L.last()$.
Precondition: it is an item in L .

$item$ $L.cyclic_succ(item\ l)$ returns the cyclic successor of item it , i.e., $L.first()$ if $it = L.last()$, $L.succ(it)$ otherwise.

$const\ E\& L.contents(item\ it)$ returns the contents $L[it]$ of item it .
Precondition: it is an item in L .

$const\ E\& L.inf(item\ it)$ returns $L.contents(it)$.
Precondition: it is an item in L .

<i>const E&</i>	<i>L.head()</i>	returns the first element of <i>L</i> , i.e. the contents of <i>L.first()</i> . <i>Precondition:</i> <i>L</i> is not empty.
<i>const E&</i>	<i>L.tail()</i>	returns the last element of <i>L</i> , i.e. the contents of <i>L.last()</i> . <i>Precondition:</i> <i>L</i> is not empty.
<i>item</i>	<i>L.push(const E& x)</i>	adds a new item $\langle x \rangle$ at the front of <i>L</i> and returns it.
<i>item</i>	<i>L.append(const E& x)</i>	appends a new item $\langle x \rangle$ to <i>L</i> and returns it.
<i>item</i>	<i>L.insert(const E& x, item pos)</i>	inserts a new item $\langle x \rangle$ after item <i>pos</i> into <i>L</i> and returns it. <i>Precondition:</i> <i>it</i> is an item in <i>L</i> .
<i>E</i>	<i>L.pop()</i>	deletes the first item from <i>L</i> and returns its contents. <i>Precondition:</i> <i>L</i> is not empty.
<i>void</i>	<i>L.delsucc.item(item it)</i>	deletes the successor of item <i>it</i> from <i>L</i> . <i>Precondition:</i> <i>it</i> is an item in <i>L</i> and has a successor.
<i>void</i>	<i>L.conc(slist<E>& L)</i>	appends list <i>L</i> ₁ to list <i>L</i> and makes <i>L</i> ₁ the empty list. <i>Precondition:</i> <i>L</i> ≠ <i>L</i> ₁ .
<i>void</i>	<i>L.clear()</i>	makes <i>L</i> the empty list.
<i>E&</i>	<i>L[item it]</i>	returns a reference to the contents of <i>it</i> .
<i>item</i>	<i>L += const E& x</i>	appends a new item $\langle x \rangle$ to <i>L</i> and returns it.

$set\langle E, set_impl \rangle S \% const\ set\langle E, set_impl \rangle \& T$	returns $S.symdiff(T)$.
$set\langle E, set_impl \rangle \& S += const\ set\langle E, set_impl \rangle \& T$	assigns $S.join(T)$ to S and returns S .
$set\langle E, set_impl \rangle \& S -= const\ set\langle E, set_impl \rangle \& T$	assigns $S.diff(T)$ to S and returns S .
$set\langle E, set_impl \rangle \& S \&= const\ set\langle E, set_impl \rangle \& T$	assigns $S.intersect(T)$ to S and returns S .
$set\langle E, set_impl \rangle \& S \% = const\ set\langle E, set_impl \rangle \& T$	assigns $S.symdiff(T)$ to S and returns S .
$bool \quad S \leq const\ set\langle E, set_impl \rangle \& T$	returns true if $S \subseteq T$, false otherwise.
$bool \quad S \geq const\ set\langle E, set_impl \rangle \& T$	returns true if $T \subseteq S$, false otherwise.
$bool \quad S == const\ set\langle E, set_impl \rangle \& T$	returns true if $S = T$, false otherwise.
$bool \quad S != const\ set\langle E, set_impl \rangle \& T$	returns true if $S \neq T$, false otherwise.
$bool \quad S < const\ set\langle E, set_impl \rangle \& T$	returns true if $S \subset T$, false otherwise.
$bool \quad S > const\ set\langle E, set_impl \rangle \& T$	returns true if $T \subset S$, false otherwise.
$bool \quad S.empty()$	returns true if S is empty, false otherwise.
$int \quad S.size()$	returns the size of S .
$void \quad S.clear()$	makes S the empty set.

Iteration

forall(x, S) { “the elements of S are successively assigned to x ” }

4. Implementation

Sets are implemented by randomized search trees [2]. Operations `insert`, `del`, `member` take time $O(\log n)$, `empty`, `size` take time $O(1)$, and `clear` takes time $O(n)$, where n is the current size of the set.

The operations `join`, `intersect`, and `diff` have the following running times: Let S_1 and S_2 be two sets of type `T` with $|S_1| = n_1$ and $|S_2| = n_2$. Then $S_1.\text{join}(S_2)$ and $S_1.\text{diff}(S_2)$ need time $O(n_2 \log(n_1 + n_2))$, $S_1.\text{intersect}(S_2)$ needs time $O(n_1 \log(n_1 + n_2))$.

7.10 Integer Sets (`int_set`)

1. Definition

An instance S of the data type `int_set` is a subset of a fixed interval $[a..b]$ of the integers, called the range of S .

```
#include <LEDA/core/int_set.h >
```

2. Creation

```
int_set S(int a, int b);
```

creates an instance S of type `int_set` for elements from $[a..b]$ and initializes it to the empty set.

```
int_set S(int n);
```

creates an instance S of type `int_set` for elements from $[0..n - 1]$ and initializes it to the empty set.

3. Operations

```
void S.insert(int x)
```

adds x to S .

Precondition: $a \leq x \leq b$.

```
void S.del(int x)
```

deletes x from S .

Precondition: $a \leq x \leq b$.

```
bool S.member(int x)
```

returns true if x in S , false otherwise.

Precondition: $a \leq x \leq b$.

```
int S.min()
```

returns the minimal integer in the range of of S .

```
int S.max()
```

returns the maximal integer in the range of of S .

```
void S.clear()
```

makes S the empty set.

In any binary operation below, S and T must have the same range:

```
int_set& S.join(const int_set& T) replaces  $S$  by  $S \cup T$  and returns it.
```

```
int_set& S.intersect(const int_set& T)
```

replaces S by $S \cap T$ and returns it.

```
int_set& S.diff(const int_set& T)
```

replaces S by $S \setminus T$ and returns it.

```
int_set& S.symdiff(const int_set& T)
```

replaces S by $(S \setminus T) \cup (T \setminus S)$ and returns it.

```
int_set& S.complement()
```

replaces S by $[a..b] \setminus S$ and returns it.

<i>int_set</i>	$S \mid \text{const } int_set \& T$	returns the union of S and T .
<i>int_set</i>	$S \& \text{const } int_set \& T$	returns the intersection of S and T .
<i>int_set</i>	$S - \text{const } int_set \& T$	returns the set difference of S and T .
<i>int_set</i>	$S \% \text{const } int_set \& T$	returns the symmetric difference of S and T .
<i>int_set</i>	$\sim S$	returns the complement of S , i.e. $[a..b] \setminus S$.

4. Implementation

Integer sets are implemented by bit vectors. Operations insert, delete, member, min and max take constant time. All other operations take time $O(b - a + 1)$.

7.11 Dynamic Integer Sets (`d_int_set`)

1. Definition

An instance S of the data type `d_int_set` is a subset of the integers.

```
#include < LEDA/core/d_int_set.h >
```

2. Creation

`d_int_set S;` creates an instance S of type `d_int_set` initializes it to the empty set.

3. Operations

<code>int</code>	<code>S.min()</code>	returns the smallest element in S . <i>Precondition:</i> S is not empty.
<code>int</code>	<code>S.max()</code>	returns the largest element in S . <i>Precondition:</i> S is not empty.
<code>void</code>	<code>S.insert(int x)</code>	adds x to S . As the sets range is expanding dynamically during insertion for the range $[S.min(), S.max()]$ inserting the extrema early saves repeated reallocation time.
<code>void</code>	<code>S.del(int x)</code>	deletes x from S .
<code>bool</code>	<code>S.member(int x)</code>	returns true if x in S , false otherwise.
<code>int</code>	<code>S.choose()</code>	returns a random element of S . <i>Precondition:</i> S is not empty.
<code>bool</code>	<code>S.empty()</code>	returns true if S is empty, false otherwise.
<code>int</code>	<code>S.size()</code>	returns the size of S .
<code>void</code>	<code>S.clear()</code>	makes S the empty set.
<code>d_int_set</code>	<code>S.join(const d_int_set& T)</code>	returns $S \cup T$.
<code>d_int_set</code>	<code>S.intersect(const d_int_set& T)</code>	returns $S \cap T$.
<code>d_int_set</code>	<code>S.diff(const d_int_set& T)</code>	returns $S - T$.
<code>d_int_set</code>	<code>S.symdiff(const d_int_set& T)</code>	returns the symmetric difference of S and T .
<code>d_int_set</code>	<code>S + const d_int_set& T</code>	returns the union $S.join(T)$.

<i>d_int_set</i>	$S - \text{const } d_int_set \& T$	returns the difference $S.diff(T)$.
<i>d_int_set</i>	$S \& \text{const } d_int_set \& T$	returns the intersection of S and T .
<i>d_int_set</i>	$S \text{const } d_int_set \& T$	returns the union $S.join(T)$.
<i>d_int_set</i>	$S \% \text{const } d_int_set \& T$	returns the symmetric difference $S.symdiff(T)$.
<i>d_int_set</i>	$S += \text{const } d_int_set \& T$	assigns $S.join(T)$ to S and returns S .
<i>d_int_set</i>	$S -= \text{const } d_int_set \& T$	assigns $S.diff(T)$ to S and returns S .
<i>d_int_set</i>	$S \&= \text{const } d_int_set \& T$	assigns $S.intersect(T)$ to S and returns S .
<i>d_int_set</i>	$S = \text{const } d_int_set \& T$	assigns $S.join(T)$ to S and returns S .
<i>d_int_set</i>	$S \% = \text{const } d_int_set \& T$	assigns $S.symdiff(T)$ to S and returns S .
<i>bool</i>	$S != \text{const } d_int_set \& T$	returns true if $S \neq T$, false otherwise.
<i>bool</i>	$S == \text{const } d_int_set \& T$	returns true if $S = T$, false otherwise.
<i>bool</i>	$S \geq \text{const } d_int_set \& T$	returns true if $T \subseteq S$, false otherwise.
<i>bool</i>	$S \leq \text{const } d_int_set \& T$	returns true if $S \subseteq T$, false otherwise.
<i>bool</i>	$S < \text{const } d_int_set \& T$	returns true if $S \subset T$, false otherwise.
<i>bool</i>	$S > \text{const } d_int_set \& T$	returns true if $T \subset S$, false otherwise.
<i>void</i>	$S.get_element_list(list<int> \& L)$	fills L with all elements stored in the set in increasing order.

Iteration

forall_elements(x, S) { “the elements of S are successively assigned to x ” }

4. Implementation

Dynamic integer sets are implemented by (dynamic) bit vectors. Operations member, empty, size, min and max take constant time. The operations clear, intersection, union and complement take time $O(b-a+1)$, where $a = \text{max}()$ and $b = \text{min}()$. The operations

insert and del also take time $O(b-a+1)$, if the bit vector has to be reallocated. Otherwise they take constant time. Iterating over all elements (with the iteration macro) requires time $O(b-a+1)$ plus the time spent in the body of the loop.

for *split*) takes time $O(m \alpha(m, n))$. The cost of a split is proportional to the size of the blocks dismantled.

5. Example

Spanning Tree Algorithms (cf. section 13).

7.13 Parameterized Partitions (Partition)

1. Definition

An instance P of the data type $Partition<E>$ consists of a finite set of items ($partition_item$) and a partition of this set into blocks. Each item has an associated information of type E .

```
#include < LEDA/core/partition.h >
```

2. Creation

$Partition<E> P;$ creates an instance P of type $Partition<E>$ and initializes it to the empty partition.

3. Operations

$partition_item$ $P.make_block(const E\& x)$

returns a new $partition_item$ it , adds the block it to partition P , and associates x with it .

$partition_item$ $P.find(partition_item p)$

returns a canonical item of the block that contains item p , i.e., iff $P.same_block(p, q)$ then $P.find(p)$ and $P.find(q)$ return the same item.
Precondition: p is an item in P .

int $P.size(partition_item p)$

returns the size of the block containing p .

int $P.number_of_blocks()$ returns the number of blocks in P .

$bool$ $P.same_block(partition_item p, partition_item q)$

returns true if p and q belong to the same block of partition P .
Precondition: p and q are items in P .

$void$ $P.union_blocks(partition_item p, partition_item q)$

unites the blocks of partition P containing items p and q .
Precondition: p and q are items in P .

$void$ $P.split(const list<partition_item>\& L)$

turns all items in L to singleton blocks.
Precondition: L is a union of blocks

$const E\&$ $P.inf(partition_item it)$

returns the information associated with it .

void

P.change_inf(partition_item it, const E& x)

changes the information associates with *it* to *x*.

Chapter 8

Dictionary Types

8.1 Dictionaries (dictionary)

1. Definition

An instance D of the parameterized data type $dictionary\langle K, I \rangle$ is a collection of items (dic_item). Every item in D contains a key from the linearly ordered data type K , called the key type of D , and an information from the data type I , called the information type of D . If K is a user-defined type, you have to provide a compare function (see Section 2.3). The number of items in D is called the size of D . A dictionary of size zero is called the empty dictionary. We use $\langle k, i \rangle$ to denote an item with key k and information i (i is said to be the information associated with key k). For each $k \in K$ there is at most one $i \in I$ with $\langle k, i \rangle \in D$.

```
#include < LEDA/core/dictionary.h >
```

2. Types

$dictionary\langle K, I \rangle::item$ the item type.

$dictionary\langle K, I \rangle::key_type$ the key type.

$dictionary\langle K, I \rangle::inf_type$ the information type.

3. Creation

```
dictionary<K, I> D;
```

creates an instance D of type $dictionary\langle K, I \rangle$ based on the linear order defined by the global $compare$ function and initializes it with the empty dictionary.

dictionary<*K*, *I*> *D*(*int* (**cmp*)(*const K*& , *const K*&));

creates an instance *D* of type *dictionary*<*K*, *I*> based on the linear order defined by the compare function *cmp* and initializes it with the empty dictionary.

4. Operations

const K& *D*.key(*dic_item it*)

returns the key of item *it*.

Precondition: *it* is an item in *D*.

const I& *D*.inf(*dic_item it*)

returns the information of item *it*.

Precondition: *it* is an item in *D*.

I& *D*[*dic_item it*]

returns a reference to the information of item *it*.

Precondition: *it* is an item in *D*.

dic_item D.insert(*const K*& *k*, *const I*& *i*)

associates the information *i* with the key *k*. If there is an item $\langle k, j \rangle$ in *D* then *j* is replaced by *i*, else a new item $\langle k, i \rangle$ is added to *D*. In both cases the item is returned.

dic_item D.lookup(*const K*& *k*)

returns the item with key *k* (nil if no such item exists in *D*).

I D.access(*const K*& *k*)

returns the information associated with key *k*.

Precondition: there is an item with key *k* in *D*.

void D.del(*const K*& *k*)

deletes the item with key *k* from *D* (null operation, if no such item exists).

void D.deItem(*dic_item it*)

removes item *it* from *D*.

Precondition: *it* is an item in *D*.

bool D.defined(*const K*& *k*)

returns true if there is an item with key *k* in *D*, false otherwise.

void D.undefine(*const K*& *k*)

deletes the item with key *k* from *D* (null operation, if no such item exists).

void D.change_inf(*dic_item it*, *const I*& *i*)

makes *i* the information of item *it*.

Precondition: *it* is an item in *D*.

void D.clear()

makes *D* the empty dictionary.

int *D.size()* returns the size of *D*.

bool *D.empty()* returns true if *D* is empty, false otherwise.

Iteration

forall_items(*it, D*) { “the items of *D* are successively assigned to *it*” }

forall_rev_items(*it, D*) { “the items of *D* are successively assigned to *it* in reverse order”
}

forall(*i, D*) { “the informations of all items of *D* are successively assigned to *i*” }

forall_defined(*k, D*) { “the keys of all items of *D* are successively assigned to *k*” }

STL compatible iterators are provided when compiled with `-DLEDA_STL_ITERATORS` (see `LEDAROOT/demo/stl/dic.c` for an example).

5. Implementation

Dictionaries are implemented by (2,4)-trees. Operations `insert`, `lookup`, `del_item`, `del` take time $O(\log n)$, `key`, `inf`, `empty`, `size`, `change_inf` take time $O(1)$, and `clear` takes time $O(n)$. Here n is the current size of the dictionary. The space requirement is $O(n)$.

6. Example

We count the number of occurrences of each string in a sequence of strings.

```
#include <LEDA/core/dictionary.h>

main()
{ dictionary<string,int> D;
  string s;
  dic_item it;

  while (cin >> s)
  { it = D.lookup(s);
    if (it==nil) D.insert(s,1);
    else D.change_inf(it,D.inf(it)+1);
  }

  forall_items(it,D) cout << D.key(it) << " : " << D.inf(it) << endl;
}
```

8.2 Dictionary Arrays (`d_array`)

1. Definition

An instance A of the parameterized data type $d_array\langle I, E \rangle$ (dictionary array) is an injective mapping from the linearly ordered data type I , called the index type of A , to the set of variables of data type E , called the element type of A . We use $A(i)$ to denote the variable with index i and we use $dom(A)$ to denote the set of “used indices”. This set is empty at the time of creation and is modified by array accesses. Each dictionary array has an associated default value $xdef$. The variable $A(i)$ has value $xdef$ for all $i \notin dom(A)$. If I is a user-defined type, you have to provide a compare function (see Section 2.3).

Related data types are *h_arrays*, *maps*, and *dictionaries*.

```
#include < LEDA/core/d_array.h >
```

2. Types

$d_array\langle I, E \rangle :: item$ the item type.

$d_array\langle I, E \rangle :: index_type$ the index type.

$d_array\langle I, E \rangle :: element_type$
 the element type.

3. Creation

$d_array\langle I, E \rangle A;$ creates an injective function a from I to the set of unused variables of type E , sets $xdef$ to the default value of type E (if E has no default value then $xdef$ stays undefined) and $dom(A)$ to the empty set, and initializes A with a .

$d_array\langle I, E \rangle A(E x);$ creates an injective function a from I to the set of unused variables of type E , sets $xdef$ to x and $dom(A)$ to the empty set, and initializes A with a .

4. Operations

$E\&$ $A[const I\& i]$ returns the variable $A(i)$.

$bool$ $A.defined(const I\& i)$
 returns true if $i \in dom(A)$ and false otherwise.

$void$ $A.undefine(const I\& i)$
 removes i from $dom(A)$ and sets $A(i)$ to $xdef$.

$void$ $A.clear()$ makes $dom(A)$ empty.

```
{
  d_array<string,string> dic;

  dic["hello"] = "hallo";
  dic["world"] = "Welt";
  dic["book"]  = "Buch";
  dic["key"]   = "Schluessel";

  string s;
  forall_defined(s,dic) cout << s << " " << dic[s] << endl;
}
```

8.3 Hashing Arrays (*h_array*)

1. Definition

An instance A of the parameterized data type $h_array\langle I, E \rangle$ (hashing array) is an injective mapping from a hashed data type I , called the index type of A , to the set of variables of arbitrary type E , called the element type of A . We use $A(i)$ to denote the variable indexed by i and we use $dom(A)$ to denote the set of “used indices”. This set is empty at the time of creation and is modified by array accesses. Each hashing array has an associated default value $xdef$. The variable $A(i)$ has value $xdef$ for all $i \notin dom(A)$. If I is a user-defined type, you have to provide a Hash function (see Section 2.3).

Related data types are *d_arrays*, *maps*, and *dictionaries*.

```
#include < LEDA/core/h_array.h >
```

2. Creation

$h_array\langle I, E \rangle A;$ creates an injective function a from I to the set of unused variables of type E , sets $xdef$ to the default value of type E (if E has no default value then $xdef$ stays undefined) and $dom(A)$ to the empty set, and initializes A with a .

$h_array\langle I, E \rangle A(E x);$
creates an injective function a from I to the set of unused variables of type E , sets $xdef$ to x and $dom(A)$ to the empty set, and initializes A with a .

$h_array\langle I, E \rangle A(E x, int\ table_sz);$
as above, but uses an initial table size of $table_sz$ instead of the default size 1.

3. Operations

$E\&$ $A[const\ I\&\ i]$ returns the variable $A(i)$.

$bool$ $A.defined(const\ I\&\ i)$
returns true if $i \in dom(A)$ and false otherwise.

$void$ $A.undefine(const\ I\&\ i)$
removes i from $dom(A)$ and sets $A(i)$ to $xdef$.

$void$ $A.clear()$ makes $dom(A)$ empty.

$void$ $A.clear(const\ E\&\ x)$ makes $dom(A)$ empty and sets $xdef$ to x .

int $A.size()$ returns $|dom(A)|$.

8.4 Maps (map)

1. Definition

An instance M of the parameterized data type $map<I, E>$ is an injective mapping from the data type I , called the index type of M , to the set of variables of data type E , called the element type of M . I must be a pointer, item, or handle type or the type `int`. We use $M(i)$ to denote the variable indexed by i . All variables are initialized to $xdef$, an element of E that is specified in the definition of M . A subset of I is designated as the domain of M . Elements are added to $dom(M)$ by the subscript operator; however, the domain may also contain indices for which the access operator was never executed.

Related data types are *d_arrays*, *h_arrays*, and *dictionaries*.

```
#include < LEDA/core/map.h >
```

2. Types

$map<I, E>::item$ the item type.
 $map<I, E>::index_type$ the index type.
 $map<I, E>::element_type$ the element type.

3. Creation

$map<I, E> M;$ creates an injective function m from I to the set of unused variables of type E , sets $xdef$ to the default value of type E (if E has no default value then $xdef$ is set to an unspecified element of E), and initializes M with m .

$map<I, E> M(E x);$ creates an injective function m from I to the set of unused variables of type E , sets $xdef$ to x , and initializes M with m .

$map<I, E> M(E x, int table_sz);$
 as above, but uses an initial table size of $table_sz$ instead of the default size 1.

4. Operations

$E\&$ $M[const I\& i]$ returns the variable $M(i)$ and adds i to $dom(M)$. If M is a const-object then $M(i)$ is read-only and i is not added to $dom(M)$.

$bool$ $M.defined(const I\& i)$ returns true if $i \in dom(M)$.

$void$ $M.clear()$ makes M empty.

$void$ $M.clear(const E\& x)$ makes M empty and sets $xdef$ to x .

$void$ $M.set_default_value(const E\& x)$
 sets $xdef$ to x .

E $M.get_default_value()$ returns the default value $xdef$.

Iteration:

forall(x, M) { “the entries $M[i]$ with $i \in dom(M)$ are successively assigned to x ” }

Note that it is *not* possible to iterate over the indices in $\text{dom}(M)$. If you need this feature use the type *h_array* instead.

5. Implementation

Maps are implemented by hashing with chaining and table doubling. Access operations $M[i]$ take expected time $O(1)$.

8.5 Two-Dimensional Maps (map2)

1. Definition

An instance M of the parameterized data type $map2\langle I1, I2, E \rangle$ is an injective mapping from the pairs in $I1 \times I2$, called the index type of M , to the set of variables of data type E , called the element type of M . I must be a pointer, item, or handle type or the type `int`. We use $M(i, j)$ to denote the variable indexed by (i, j) and we use $dom(M)$ to denote the set of “used indices”. This set is empty at the time of creation and is modified by `map2` accesses.

Related data types are `map`, `d_arrays`, `h_arrays`, and `dictionaries`.

```
#include < LEDA/core/map2.h >
```

2. Types

$map2\langle I1, I2, E \rangle:: item$ the item type.

$map2\langle I1, I2, E \rangle:: index_type1$
 the first index type.

$map2\langle I1, I2, E \rangle:: index_type2$
 the second index type .

$map2\langle I1, I2, E \rangle:: element_type$
 the element type.

3. Creation

$map2\langle I1, I2, E \rangle M;$ creates an injective function m from $I1 \times I2$ to the set of unused variables of type E , sets $xdef$ to the default value of type E (if E has no default value then $xdef$ stays undefined) and $dom(M)$ to the empty set, and initializes M with m .

$map2\langle I1, I2, E \rangle M(E x);$
 creates an injective function m from $I1 \times I2$ to the set of unused variables of type E , sets $xdef$ to x and $dom(M)$ to the empty set, and initializes M with m .

4. Operations

$E\&$ $M(const I1\& i, const I2\& j)$
 returns the variable $M(i)$.

$bool$ $M.defined(const I1\& i, const I2\& j)$
 returns true if $i \in dom(M)$ and false otherwise.

void $M.\text{clear}()$ clears M by making $\text{dom}(M)$ the empty set.

5. Implementation

Maps are implemented by hashing with chaining and table doubling. Access operations $M(i, j)$ take expected time $O(1)$.

8.6 Sorted Sequences (sortseq)

1. Definition

An instance S of the parameterized data type $sortseq\langle K, I \rangle$ is a sequence of items (seq_item). Every item contains a key from a linearly ordered data type K , called the key type of S , and an information from a data type I , called the information type of S . If K is a user-defined type, you have to provide a compare function (see Section 2.3). The number of items in S is called the size of S . A sorted sequence of size zero is called empty. We use $\langle k, i \rangle$ to denote a seq_item with key k and information i (called the information associated with key k). For each k in K there is at most one item $\langle k, i \rangle$ in S and if item $\langle k1, i1 \rangle$ precedes item $\langle k2, i2 \rangle$ in S then $k1 < k2$.

Sorted sequences are a very powerful data type. They can do everything that dictionaries and priority queues can do. They also support many other operations, in particular *finger searches* and operations *conc*, *split*, *merge*, *reverse_items*, and *delete_subsequence*.

The key type K must be linearly ordered. The linear order on K may change over time subject to the condition that the order of the elements that are currently in the sorted sequence remains stable. More precisely, whenever an operation (except for *reverse_items*) is applied to a sorted sequence S , the keys of S must form an increasing sequence according to the currently valid linear order on K . For operation *reverse_items* this must hold after the execution of the operation. An application of sorted sequences where the linear order on the keys evolves over time is the plane sweep algorithm for line segment intersection. This algorithm sweeps an arrangement of segments by a vertical sweep line and keeps the intersected segments in a sorted sequence sorted according to the y-coordinates of their intersections with the sweep line. For intersecting segments this order depends on the position of the sweep line.

Sorted sequences support finger searches. A finger search takes an item it in a sorted sequence and a key k and searches for the key in the sorted sequence containing the item. The cost of a finger search is proportional to the logarithm of the distance of the key from the start of the search. A finger search does not need to know the sequence containing the item. We use IT to denote the sequence containing it . In a call $S.finger_search(it, k)$ the types of S and IT must agree but S may or may not be the sequence containing it .

```
#include < LEDA/core/sortseq.h >
```

2. Types

$sortseq\langle K, I \rangle:: item$ the item type seq_item .

$sortseq\langle K, I \rangle:: key_type$ the key type K .

$sortseq\langle K, I \rangle:: inf_type$ the information type I .

3. Creation

sortseq<*K*, *I*> *S*;

creates an instance *S* of type *sortseq*<*K*, *I*> based on the linear order defined by the global *compare* function and initializes it to the empty sorted sequence.

sortseq<*K*, *I*> *S*(*int* (**cmp*) (*const K*& , *const K*&));

creates an instance *S* of type *sortseq*<*K*, *I*> based on the linear order defined by the compare function *cmp* and initializes it with the empty sorted sequence.

4. Operations

const K& *S*.key(*seq_item* *it*)

returns the key of item *it*.

const I& *S*.inf(*seq_item* *it*)

returns the information of item *it*.

I& *S*[*seq_item* *it*]

returns a reference to the information of item *it*.
Precondition: *it* is an item in *S*.

seq_item *S*.lookup(*const K*& *k*)

returns the item with key *k* (*nil* if there is no such item).

seq_item *S*.finger.lookup(*const K*& *k*)

equivalent to *S*.lookup(*k*)

seq_item *S*.finger.lookup_from_front(*const K*& *k*)

equivalent to *S*.lookup(*k*)

seq_item *S*.finger.lookup_from_rear(*const K*& *k*)

equivalent to *S*.lookup(*k*)

seq_item *S*.locate(*const K*& *k*)

returns the item $\langle k1, i \rangle$ in *S* such that *k1* is minimal with $k1 \geq k$ (*nil* if no such item exists).

seq_item *S*.finger.locate(*const K*& *k*)

equivalent to *S*.locate(*k*)

seq_item *S*.finger.locate_from_front(*const K*& *k*)

equivalent to *S*.locate(*k*)

seq_item *S*.finger.locate_from_rear(*const K*& *k*)

equivalent to *S*.locate(*k*)

seq_item *S*.locate_succ(*const K*& *k*)

equivalent to *S*.locate(*k*)

- seq_item* $S.succ(const\ K\&\ k)$ equivalent to $S.locate(k)$
- seq_item* $S.finger.locate.succ(const\ K\&\ k)$
equivalent to $S.locate(k)$
- seq_item* $S.finger.locate.succ.from.front(const\ K\&\ k)$
equivalent to $S.locate(k)$
- seq_item* $S.finger.locate.succ.from.rear(const\ K\&\ k)$
equivalent to $S.locate(k)$
- seq_item* $S.locate.pred(const\ K\&\ k)$
returns the item $\langle k1, i \rangle$ in S such that $k1$ is maximal with $k1 \leq k$ (*nil* if no such item exists).
- seq_item* $S.pred(const\ K\&\ k)$ equivalent to $S.locate.pred(k)$
- seq_item* $S.finger.locate.pred(const\ K\&\ k)$
equivalent to $S.locate.pred(k)$
- seq_item* $S.finger.locate.pred.from.front(const\ K\&\ k)$
equivalent to $S.locate.pred(k)$
- seq_item* $S.finger.locate.pred.from.rear(const\ K\&\ k)$
equivalent to $S.locate.pred(k)$
- seq_item* $S.finger.lookup(seq_item\ it,\ const\ K\&\ k)$
equivalent to $IT.lookup(k)$ where IT is the sorted sequence containing it .
Precondition: S and IT must have the same type
- seq_item* $S.finger.locate(seq_item\ it,\ const\ K\&\ k)$
equivalent to $IT.locate(k)$ where IT is the sorted sequence containing it .
Precondition: S and IT must have the same type.
- seq_item* $S.finger.locate.succ(seq_item\ it,\ const\ K\&\ k)$
equivalent to $IT.locate.succ(k)$ where IT is the sorted sequence containing it .
Precondition: S and IT must have the same type
- seq_item* $S.finger.locate.pred(seq_item\ it,\ const\ K\&\ k)$
equivalent to $IT.locate.pred(k)$ where IT is the sorted sequence containing it .
Precondition: S and IT must have the same type.
- seq_item* $S.min_item()$ returns the item with minimal key (*nil* if S is empty).

<i>seq_item</i>	<i>S.max_item()</i>	returns the item with maximal key (<i>nil</i> if <i>S</i> is empty).
<i>seq_item</i>	<i>S.succ(seq_item it)</i>	returns the successor item of <i>it</i> in the sequence containing <i>it</i> (<i>nil</i> if there is no such item).
<i>seq_item</i>	<i>S.pred(seq_item x)</i>	returns the predecessor item of <i>it</i> in the sequence containing <i>it</i> (<i>nil</i> if there is no such item).
<i>seq_item</i>	<i>S.insert(const K& k, const I& i)</i>	associates information <i>i</i> with key <i>k</i> : If there is an item $\langle k, j \rangle$ in <i>S</i> then <i>j</i> is replaced by <i>i</i> , else a new item $\langle k, i \rangle$ is added to <i>S</i> . In both cases the item is returned.
<i>seq_item</i>	<i>S.insert_at(seq_item it, const K& k, const I& i)</i>	Like <i>IT.insert(k, i)</i> where <i>IT</i> is the sequence containing item <i>it</i> . <i>Precondition:</i> <i>it</i> is an item in <i>IT</i> with $key(it)$ is maximal with $key(it) < k$ or $key(it)$ is minimal with $key(it) > k$ or if $key(it) = k$ then $inf(it)$ is replaced by <i>i</i> . <i>S</i> and <i>IT</i> have the same type.
<i>seq_item</i>	<i>S.insert_at(seq_item it, const K& k, const I& i, int dir)</i>	Like <i>IT.insert(k, i)</i> where <i>IT</i> is the sequence containing item <i>it</i> . <i>Precondition:</i> <i>it</i> is an item in <i>IT</i> with $key(it)$ is maximal with $key(it) < k$ if <i>dir</i> = <i>leda::before</i> or $key(it)$ is minimal with $k < key(it)$ if <i>dir</i> = <i>leda::behind</i> or if $key(it) = k$ then $inf(it)$ is replaced by <i>i</i> . <i>S</i> and <i>IT</i> have the same type.
<i>int</i>	<i>S.size()</i>	returns the size of <i>S</i> .
<i>bool</i>	<i>S.empty()</i>	returns true if <i>S</i> is empty, false otherwise.
<i>void</i>	<i>S.clear()</i>	makes <i>S</i> the empty sorted sequence.
<i>void</i>	<i>S.reverse_items(seq_item a, seq_item b)</i>	the subsequence of <i>IT</i> from <i>a</i> to <i>b</i> is reversed, where <i>IT</i> is the sequence containing <i>a</i> and <i>b</i> . <i>Precondition:</i> <i>a</i> appears before <i>b</i> in <i>IT</i> .
<i>void</i>	<i>S.flip_items(seq_item a, seq_item b)</i>	equivalent to <i>S.reverse_items(a, b)</i> .

void *S.del(const K& k)*

removes the item with key *k* from *S* (null operation if no such item exists).

void *S.delItem(seq_item it)*

removes the item *it* from the sequence containing *it*.

void *S.change_inf(seq_item it, const I& i)*

makes *i* the information of item *it*.

void *S.split(seq_item it, sortseq<K, I, seq_impl>& S1, sortseq<K, I, seq_impl>& S2, int dir = leda::behind)*

splits *IT* at item *it*, where *IT* is the sequence containing *it*, into sequences *S1* and *S2* and makes *IT* empty (if distinct from *S1* and *S2*). More precisely, if $IT = x_1, \dots, x_{k-1}, it, x_{k+1}, \dots, x_n$ and *dir* = *leda::behind* then $S1 = x_1, \dots, x_{k-1}, it$ and $S2 = x_{k+1}, \dots, x_n$. If *dir* = *leda::before* then *S2* starts with *it* after the split.

void *S.delete_subsequence(seq_item a, seq_item b, sortseq<K, I, seq_impl>& S1)*

deletes the subsequence starting at *a* and ending at *b* from the sequence *IT* containing both and assigns the subsequence to *S1*.

Precondition: *a* and *b* belong to the same sequence *IT*, *a* is equal to or before *b* and *IT* and *S1* have the same type.

sortseq<K, I, seq_impl>& S.conc(sortseq<K, I, seq_impl>& S1, int dir = leda::behind)

appends *S1* at the front (*dir* = *leda::before*) or rear (*dir* = *leda::behind*) end of *S*, makes *S1* empty and returns *S*.

Precondition: $S.key(S.max_item()) < S1.key(S1.min_item())$ if *dir* = *leda::behind* and $S1.key(S1.max_item()) < S.key(S.min_item())$ if *dir* = *leda::before*.

void *S.merge(sortseq<K, I, seq_impl>& S1)*

merges the sequence *S1* into sequence *S* and makes *S1* empty.

Precondition: all keys are distinct.

void *S.print ostream& out, string s, char c = ' ')*

prints *s* and all elements of *S* separated by *c* onto stream *out*.

void *S.print(string s, char c = ' ')*

equivalent to *S.print(cout, s, c)*.

bool *S == const sortseq<K, I, seq_impl>& S1*

returns *true* if *S* agrees with *S1* componentwise and *false* otherwise

sortseq<K, I, seq_impl> sortseq<K, I>::my_sortseq(seq_item it)*

returns a pointer to the *sortseq* containing *it*.

Precondition: The type of the *sortseq* containing *it* must be *sortseq<K, I>*.

Iteration

forall_items(*it*, *S*) { “the items of *S* are successively assigned to *it*” }

forall_rev_items(*it*, *S*) { “the items of *S* are successively assigned to *it* in reverse order”
}

forall(*i*, *S*) { “the informations of all items of *S* are successively assigned to *i*” }

forall_defined(*k*, *S*) { “the keys of all items of *S* are successively assigned to *k*” }

5. Implementation

Sorted sequences are implemented by skiplists [77]. Let n denote the current size of the sequence. Operations *insert*, *locate*, *lookup* and *del* take time $O(\log n)$, operations *succ*, *pred*, *max*, *min_item*, *key*, *inf*, *insert_at* and *del_item* take time $O(1)$. *clear* takes time $O(n)$ and *reverse_items* $O(l)$, where l is the length of the reversed subsequence. *Finger_lookup*(x) and *finger_locate*(x) take time $O(\log \min(d, n - d))$ if x is the d -th item in S . *Finger_lookup_from_front*(x) and *finger_locate_from_front*(x) take time $O(\log d)$ if x is the d -th item in S . *Finger_lookup_from_rear*(x) and *finger_locate_from_rear*(x) take time $O(\log d)$ if x is the $n - d$ -th item in S . *Finger_lookup*(it, x) and *finger_locate*(it, x) take time $O(\log \min(d, n - d))$ where d is the number of items between it and the item containing x . Note that $\min(d, n - d)$ is the smaller of the distances from it to x if sequences are viewed as circularly closed. *Split*, *delete_subsequence* and *conc* take time $O(\log \min(n_1, n_2))$ where n_1 and n_2 are the sizes of the results of *split* and *delete_subsequence* and the arguments of *conc* respectively. *Merge* takes time $O(\log((n_1 + n_2)/n_1))$ where n_1 and n_2 are the sizes of the two arguments. The space requirement of sorted sequences is linear in the length of the sequence (about $25.5n$ Bytes for a sequence of size n plus the space for the keys and the informations.).

6. Example

We use a sorted sequence to list all elements in a sequence of strings lying lexicographically between two given search strings.

```
#include <LEDA/core/sortseq.h>
#include <iostream>

using leda::sortseq;
using leda::string;
using leda::seq_item;
using std::cin;
using std::cout;
```

```
int main()
{
    sortseq<string, int> S;
    string s1, s2;

    cout << "Input a sequence of strings terminated by 'STOP'\n";
    while (cin >> s1 && s1 != "STOP")
        S.insert(s1, 0);

    while(true) {
        cout << "\n\nInput a pair of strings:\n";
        cin >> s1 >> s2;
        cout << "All strings s with " << s1 <<" <= s <= " << s2 << ":";
        if(s2 < s1) continue;
        seq_item last = S.locate_pred(s2);
        seq_item first = S.locate(s1);
        if ( !first || !last || first == S.succ(last) ) continue;
        seq_item it = first;
        while(true) {
            cout << "\n" << S.key(it);
            if(it == last) break;
            it = S.succ(it);
        }
    }
}
```

Further examples can be found in section Sorted Sequences of [64].

Chapter 9

Priority Queues

9.1 Priority Queues (`p_queue`)

1. Definition

An instance Q of the parameterized data type $p_queue\langle P, I \rangle$ is a collection of items (type pq_item). Every item contains a priority from a linearly ordered type P and an information from an arbitrary type I . P is called the priority type of Q and I is called the information type of Q . If P is a user-defined type, you have to define the linear order by providing the compare function (see Section 2.3). The number of items in Q is called the size of Q . If Q has size zero it is called the empty priority queue. We use $\langle p, i \rangle$ to denote a pq_item with priority p and information i .

Remark: Iteration over the elements of Q using iteration macros such as *forall* is not supported.

```
#include < LEDA/core/p_queue.h >
```

2. Types

$p_queue\langle P, I \rangle::item$	the item type.
$p_queue\langle P, I \rangle::prio_type$	the priority type.
$p_queue\langle P, I \rangle::inf_type$	the information type.

3. Creation

$p_queue\langle P, I \rangle Q;$	creates an instance Q of type $p_queue\langle P, I \rangle$ based on the linear order defined by the global compare function $compare(const P\&, const P\&)$ and initializes it with the empty priority queue.
-----------------------------------	---

$p_queue<P, I>$ $Q(int (*cmp)(const P\& , const P\&));$

creates an instance Q of type $p_queue<P, I>$ based on the linear order defined by the compare function cmp and initializes it with the empty priority queue. *Precondition:* cmp must define a linear order on P .

4. Operations

$const P\&$	$Q.prio(pq_item\ it)$	returns the priority of item it . <i>Precondition:</i> it is an item in Q .
$const I\&$	$Q.inf(pq_item\ it)$	returns the information of item it . <i>Precondition:</i> it is an item in Q .
$I\&$	$Q[pq_item\ it]$	returns a reference to the information of item it . <i>Precondition:</i> it is an item in Q .
pq_item	$Q.insert(const\ P\&\ x,\ const\ I\&\ i)$	adds a new item $\langle x, i \rangle$ to Q and returns it.
pq_item	$Q.find_min()$	returns an item with minimal priority (nil if Q is empty).
P	$Q.del_min()$	removes the item $it = Q.find_min()$ from Q and returns the priority of it. <i>Precondition:</i> Q is not empty.
$void$	$Q.del_item(pq_item\ it)$	removes the item it from Q . <i>Precondition:</i> it is an item in Q .
$void$	$Q.change_inf(pq_item\ it,\ const\ I\&\ i)$	makes i the new information of item it . <i>Precondition:</i> it is an item in Q .
$void$	$Q.decrease_p(pq_item\ it,\ const\ P\&\ x)$	makes x the new priority of item it . <i>Precondition:</i> it is an item in Q and x is not larger than $prio(it)$.
int	$Q.size()$	returns the size of Q .
$bool$	$Q.empty()$	returns true, if Q is empty, false otherwise.
$void$	$Q.clear()$	makes Q the empty priority queue.

5. Implementation

Priority queues are implemented by binary heaps [91]. Operations `insert`, `del_item`, `del_min` take time $O(\log n)$, `find_min`, `decrease_p`, `prio`, `inf`, `empty` take time $O(1)$ and `clear` takes time $O(n)$, where n is the size of Q . The space requirement is $O(n)$.

6. Example

Dijkstra's Algorithm (cf. section 13)

9.2 Bounded Priority Queues (`b_priority_queue`)

1. Definition

An instance Q of the parameterized data type `b_priority_queue<I>` is a collection of items (type `b_pq_item`). Every item contains a priority from a fixed interval $[a..b]$ of integers (type `int`) and an information from an arbitrary type I . The number of items in Q is called the size of Q . If Q has size zero it is called the empty priority queue. We use $\langle p, i \rangle$ to denote a `b_pq_item` with priority $p \in [a..b]$ and information i .

Remark: Iteration over the elements of Q using iteration macros such as `forall` is not supported.

```
#include < LEDA/core/b_prio.h >
```

2. Creation

```
b_priority_queue<I> Q(int a, int b);
```

creates an instance Q of type `b_priority_queue<I>` with key type $[a..b]$ and initializes it with the empty priority queue.

3. Operations

```
b_pq_item Q.insert(int key, const I& inf)
```

adds a new item $\langle key, inf \rangle$ to Q and returns it.
Precondition: $key \in [a..b]$

```
void Q.decrease_key(b_pq_item it, int newkey)
```

makes *newkey* the new priority of item *it*.
Precondition: *it* is an item in Q , $newkey \in [a..b]$ and *newkey* is not larger than $prio(it)$.

```
void Q.delItem(b_pq_item x)
```

deletes item *it* from Q .
Precondition: *it* is an item in Q .

```
int Q.prio(b_pq_item x)
```

returns the priority of item *i*.
Precondition: *it* is an item in Q .

```
const I& Q.inf(b_pq_item x)
```

returns the information of item *i*.
Precondition: *it* is an item in Q .

```
b_pq_item Q.find_min()
```

returns an item with minimal priority (*nil* if Q is empty).

```
I Q.del_min()
```

deletes the item $it = Q.find_min()$ from Q and returns the information of *it*.
Precondition: Q is not empty.

```
void Q.clear()
```

makes Q the empty bounded priority queue.

<i>int</i>	<code>Q.size()</code>	returns the size of Q .
<i>bool</i>	<code>Q.empty()</code>	returns true if Q is empty, false otherwise.
<i>int</i>	<code>Q.lower_bound()</code>	returns the lower bound of the priority interval $[a..b]$.
<i>int</i>	<code>Q.upper_bound()</code>	returns the upper bound of the priority intervall $[a..b]$.

4. Implementation

Bounded priority queues are implemented by arrays of linear lists. Operations `insert`, `find_min`, `del_item`, `decrease_key`, `key`, `inf`, and `empty` take time $O(1)$, `del_min` (= `del_item` for the minimal element) takes time $O(d)$, where d is the distance of the minimal element to the next bigger element in the queue (= $O(b - a)$ in the worst case). `clear` takes time $O(b - a + n)$ and the space requirement is $O(b - a + n)$, where n is the current size of the queue.

Chapter 10

Lossless Compression

Before we go into the details of the classes belonging to this module we want to give an overview of the different components and how they interact. We start with an example. Suppose you want to write a string to a compressed file named “foo” and read it back from the file. Then you can use the following program:

```
#include <LEDA/basics/string.h>
#include <LEDA/coding/compress.h> // contains all compression classes

using namespace leda;

typedef HuffmanCoder Coder;

int main()
{
    string str = "Hello World";

    encoding_ofstream<Coder> out("foo");
    out << str << "\n";
    out.close();
    if (out.fail()) std::cout << "error writing foo" << "\n";

    decoding_ifstream<Coder> in("foo");
    str.read_line(in);
    in.close();
    if (in.fail()) std::cout << "error reading foo" << "\n";

    std::cout << "decoded string: " << str << "\n";

    return 0;
}
```

In the example above we used the classes *encoding_ofstream* and *decoding_ifstream* with LEDA datatypes only. We want to emphasize that they work together with user-defined types as well. All operations and operators (<< and >>) defined for C++ streams can be applied to them, too.

Assume that you want to send the file “foo” to a friend over the internet and you want to make sure that its contents do not get corrupted. Then you can easily add a checksum to your file. All you have to do is to replace the coder in the `typedef`-statement by `CoderPipe2<MD5SumCoder, HuffmanCoder>`. The class *CoderPipe2* combines the two LEDA coders *MD5SumCoder* (the checksummer) and *HuffmanCoder* into a single coder. If the pipe is used for encoding, then the *MD5SumCoder* is used first and the *HuffmanCoder* is applied to its output. In decoding mode the situation is reversed.

The standard behaviour of a checksummer like *MD5SumCoder* is as follows: In encoding mode it reads the input stream and computes a checksum; the output data basically consists of the input data with the checksum appended. In decoding mode the checksum is stripped from the input data and verified. If the input is corrupted the failure flag of the coder is set to signal this.

Suppose further that your friend has received the encoded file “foo” and wants to decode it but he does not know which combination of coders you have used for encoding. This is not a problem because LEDA provides a class called *AutoDecoder* which can be used to decode any stream that has been encoded by LEDA. The complete code for this extended example is depicted below:

```
#include <LEDA/basics/string.h>
#include <LEDA/coding/compress.h>

using namespace leda;

typedef CoderPipe2<MD5SumCoder, HuffmanCoder> Coder;

int main()
{
    string str = "Hello World";

    // your code ...
    encoding_ofstream<Coder> out("foo");
    out << str << "\n";
    out.close();
    if (out.fail()) std::cout << "error writing foo" << "\n";

    // your friend's code ...
    autodecoding_ifstream in("foo");
    // autodecoding_ifstream = decoding_istream<AutoDecoder>
    str.read_line(in);
    in.finish(); // read till the end before closing (-> verify checksum)
    if (in.fail()) std::cout << "decoding error, foo corrupted" << "\n";
    std::cout << "decoded string: " << str << "\n";

    return 0;
}
```

This example shows how easy it is to add compression to existing applications: You include the header “LEDA/coding/compress.h”, which makes all classes in the com-

pression module available. Then you simply replace every occurrence of *ofstream* by *encoding_ofstream<Coder>* and every occurrence of *ifstream* by *autodecoding_ifstream*.

Of course, you can also use the LEDA coders in file mode. This means you can encode a file “foo” into a file “bar” and decode “bar” again. The example below shows how. We also demonstrate a nice feature of the *AutoDecoder*: If you query a description *after* the decoding the object tells you which combination has been used for encoding the input.

```
#include <LEDA/coding/compress.h>

using namespace leda;

typedef CoderPipe2<MD5SumCoder, HuffmanCoder> Coder;

int main()
{
    Coder coder("foo", "bar");
    coder.encode();
    if (coder.fail()) std::cout << "error encoding foo" << "\n";

    AutoDecoder auto("bar", "foo");
    auto.decode();
    if (auto.fail()) std::cout << "error decoding bar" << "\n";

    std::cout << "Decoding info: " << auto.get_description() << "\n";

    return 0;
}
```

More examples can be found in `$LEDAROOT/test/compression`. There we show in particular how the user can build a LEDA compliant coder which integrates seamlessly with the *AutoDecoder*.

Below we give a few suggestions about when to use which coder:

- maximum compression needed, speed and memory usage not so important:
use the *PPMIICoder*.
- high compression needed, main memory < 2MB, speed less relevant:
use a coder from the BWT-family:
CoderPipe4<BWTCoder, MTF2Coder, RLE0Coder, A0Coder>
CoderPipe3<BWTCoder, MTFCoder, A0Coder>.
- maximum speed and good compression needed:
use the *DeflateCoder*.

10.1 Adaptive Arithmetic Coder (A0Coder)

1. Definition

An instance C of *A0Coder* is an adaptive arithmetic coder of order zero (which explains the “0” in the class name). When the coder encodes a stream it counts the frequencies of the characters that have occurred so far in order to obtain a model of the probabilities for the future characters. The model is called order zero because it does not take into account that the probability of a character c may depend on the characters that precede it. (E.g., in an English text the probability that the next character is a “u” is very high if the current character is a “q”. The *PPMII*Coder in Section 10.3 takes this into account.) The advantage of arithmetic coding [92] is that a character in the source stream can be encoded by a fractional number of bits in the target stream, which leads to good results in practice.

The coder is called *adaptive* because the model evolves gradually while the coder scans its input. In contrast to that a *static* coder reads the whole input once before it generates a model. During the actual encoding (in a second scan) the model remains fixed. The adaptive coder resets and/or scales its model when the number of characters read since the last reset/scaling exceeds a certain threshold. Both thresholds can be controlled by the user.

```
#include < LEDA/coding/arithmetic_coding.h >
```

2. Creation

```
A0Coder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
          bool own_streams = false);
```

creates an instance C which uses the given source and target streams. If *own_streams* is set, then C is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of C .

```
A0Coder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance C which uses file-streams for input and output.

3. Operations

Standard Operations

```
void      C.encode()      encodes the source stream and writes the output to
                        the target stream.
```

```
void      C.decode()      decodes the source stream and writes the output to
                        the target stream.
```

- uint32* *C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 encodes the memory chunk starting at *in_buf* with size *in_len* into the buffer starting at *out_buf* with size *out_len*. The function returns actual length of the encoded chunk which may be smaller than *out_len*. If the output buffer is too small for the encoded data the failure flag will be set (see below).
- uint32* *C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
- streambuf** *C.get_src_stream()* returns the current source stream.
- void* *C.set_src_stream(streambuf * src_stream, bool own_stream = false)*
 sets the source stream (cf. constructor).
- void* *C.set_src_file(const char * file_name)*
 sets a file as source stream.
- streambuf** *C.get_tgt_stream()* returns the current target stream.
- void* *C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)*
 sets the target stream (cf. constructor).
- void* *C.set_tgt_file(const char * file_name)*
 sets a file as target stream.
- void* *C.reset(bool keep_thresholds = true)*
 puts *C* in the same state as the default constructor. If *keep_thresholds* is false the thresholds are set to their default values.
- bool* *C.failed()* returns *true* if an error occurred.
- bool* *C.finished()* returns *true* if the coding is finished.
- string* *C.get_description()* provides a description for *C*.

Additional Operations

- uint32* *C.get_reset_threshold()*
 returns the current threshold for resetting the model.
- void* *C.set_reset_threshold(uint32 t)*
 sets the threshold for resetting the model.

uint32 `C.get_scale_threshold()`

returns the current threshold for scaling the model.

uint32 `C.get_max_scale_threshold()`

returns the maximum threshold S for scaling the model.

void `C.set_scale_threshold(uint32 t)`

sets the threshold for scaling the model.

Precondition: $512 \leq t \leq S$

10.2 Static Arithmetic Coder (A0sCoder)

1. Definition

An instance C of $A0sCoder$ is a static arithmetic coder of order zero. (We assume that the reader is familiar with the definition of the class $A0Coder$ from the previous section.) $A0sCoder$ is called *static* because it uses a fixed model for encoding. The input is scanned twice. In the first scan the frequencies of the characters are counted. This information is used to precompute the model. In the second scan the actual coding takes place. Since the model is fixed the static coder is usually faster than the adaptive coder (despite the two scans) but the compression rates are often slightly inferior.

```
#include < LEDA/coding/arithmetic_coding.h >
```

2. Creation

```
A0sCoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
            bool own_streams = false);
```

creates an instance C which uses the given source and target streams. If *own_streams* is set, then C is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of C .

```
A0sCoder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance C which uses file-streams for input and output.

3. Operations

Standard Operations

<i>void</i>	$C.encode()$	encodes the source stream and writes the output to the target stream.
<i>void</i>	$C.decode()$	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	$C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)$	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).

<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

10.3 Prediction by Partial Matching (PPMIICoder)

1. Definition

The *PPMIICoder* is based on the compression scheme “Prediction by Partial Matching with Information Inheritance” by D. Shkarin [81].

This coder works as follows: Suppose we have processed the first $n-1$ symbols $x_1 \dots x_{n-1}$ of the stream. Before reading the next symbol x_n we try to guess it, i.e. for every symbol s we estimate the probability $p(s)$ for the event “ $x_n = s$ ”. This probability distribution determines how the next symbol is encoded: The higher $p(s)$, the fewer bits are used for encoding s . If our estimation is good, which means that $p(x_n)$ is high, then we obtain a good compression rate.

In order to predict the probability distribution for the n th symbol the PPM approach considers the preceding k symbols $x_{n-k} \dots x_{n-1}$. We call these symbols the *context* of x_n and k the order of the model. (For $k = 0$ we obtain the order-0 model from the previous section.) E.g., if the current context is “req”, then we should predict the letter “u” as next symbol with high probability.

PPMII is a variant of PPM which usually achieves very accurate estimations.

The *PPMIICoder* combines very good compression rates with acceptable speed. (Shkarin [81] reports that his coder outperforms ZIP and BZIP2 with respect to compression rates and speed.) The only disadvantage of this coder is that it needs a fair amount of main memory to store the model. However, the user can set an upper bound on the memory usage. And he can specify which model restoration method the coder shall apply when it runs out of memory:

- *mr_restart* (default):
The model is deleted completely and rebuilt from scratch. This method is fast.
- *mr_cut_off*:
Parts of the model are freed to gain memory. This method is optimal for so-called quasistationary sources. It usually gives better compression but it is slower.
- *mr_freeze*:
The model is not extended any more. This method is optimal for so-called stationary sources. (We want to point out that data streams arising in practical applications usually do not behave like a stationary source.)

```
#include < LEDA/coding/PPMII.h >
```

2. Types

```
PPMIICoder::mr_method { mr_restart, mr_cut_off, mr_freeze }  
the different model restoration modes.
```

3. Creation

PPMIICoder $C(\text{streambuf} * \text{src_stream} = 0, \text{streambuf} * \text{tgt_stream} = 0, \text{bool } \text{own_streams} = \text{false});$

creates an instance C which uses the given source and target streams. If own_streams is set, then C is responsible for the destruction of the streams, otherwise the pointers src_stream and tgt_stream must be valid during the life-time of C .

PPMIICoder $C(\text{const char} * \text{src_file_name}, \text{const char} * \text{tgt_file_name});$

creates an instance C which uses file-streams for input and output.

4. Operations

Standard Operations

- | | | |
|-------------------|--|---|
| <i>void</i> | $C.\text{encode}()$ | encodes the source stream and writes the output to the target stream. |
| <i>void</i> | $C.\text{decode}()$ | decodes the source stream and writes the output to the target stream. |
| <i>uint32</i> | $C.\text{encode_memory_chunk}(\text{const char} * \text{in_buf}, \text{uint32 } \text{in_len}, \text{char} * \text{out_buf}, \text{uint32 } \text{out_len})$ | encodes the memory chunk starting at in_buf with size in_len into the buffer starting at out_buf with size out_len . The function returns actual length of the encoded chunk which may be smaller than out_len . If the output buffer is too small for the encoded data the failure flag will be set (see below). |
| <i>uint32</i> | $C.\text{decode_memory_chunk}(\text{const char} * \text{in_buf}, \text{uint32 } \text{in_len}, \text{char} * \text{out_buf}, \text{uint32 } \text{out_len})$ | decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function. |
| <i>streambuf*</i> | $C.\text{get_src_stream}()$ | returns the current source stream. |
| <i>void</i> | $C.\text{set_src_stream}(\text{streambuf} * \text{src_stream}, \text{bool } \text{own_stream} = \text{false})$ | sets the source stream (cf. constructor). |
| <i>void</i> | $C.\text{set_src_file}(\text{const char} * \text{file_name})$ | sets a file as source stream. |
| <i>streambuf*</i> | $C.\text{get_tgt_stream}()$ | returns the current target stream. |
| <i>void</i> | $C.\text{set_tgt_stream}(\text{streambuf} * \text{tgt_stream}, \text{bool } \text{own_Stream} = \text{false})$ | sets the target stream (cf. constructor). |

<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset(bool keep_parameters = true)</i>	puts <i>C</i> in the same state as the default constructor. If <i>keep_parameters</i> is false the parameters are set to their default values.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

Additional Operations

<i>uint16</i>	<i>C.get_model_memory_bound()</i>	returns how much memory (in MB) <i>C</i> is allowed to use for storing the model.
<i>void</i>	<i>C.set_model_memory_bound(uint16 max_mem)</i>	determines the amount of memory available for the model (in MB).
<i>byte</i>	<i>C.get_model_order()</i>	returns the order of the model.
<i>void</i>	<i>C.set_model_order(byte order)</i>	sets the order of the model. <i>Precondition: order</i> \in [2..16].
<i>mr_method</i>	<i>C.get_model_restoration_method()</i>	returns the model restoration method.
<i>void</i>	<i>C.set_model_restoration_method(mr_method method)</i>	sets the model restoration method.

5. Implementation

Our implementation encapsulates the code by D. Shkarin (the implementation of the PPMII model) and by D. Subbotin (the implementation of the range coder).

10.4 Deflation/Inflation Coder (DeflateCoder)

1. Definition

The class *DeflateCoder* encapsulates the algorithms “deflation” and “inflation” from the zlib-library by J.-L. Gilly and M. Adler (see www.zlib.org).

Both algorithms use two buffers (for encoded and decoded data). The user can control the size of each buffer. In addition he can fine-tune some parameters of the algorithm, which gives him a trade-off between compression rate and speed.

This coder is fast, gives good compression rates and has moderate memory requirements.

```
#include < LEDA/coding/deflate.h >
```

2. Creation

```
DeflateCoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
               bool own_streams = false, uint32 enc_buffer_sz = DefaultBufferSize,
               uint32 dec_buffer_sz = DefaultBufferSize);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*. (In addition the sizes of the two buffers may be specified.)

```
DeflateCoder C(const char * src_file_name, const char * tgt_file_name,
               uint32 enc_buffer_sz = DefaultBufferSize,
               uint32 dec_buffer_sz = DefaultBufferSize);
```

creates an instance *C* which uses file-streams for input and output. (In addition the sizes of the two buffers may be specified.)

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.

- uint32* *C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 encodes the memory chunk starting at *in_buf* with size *in_len* into the buffer starting at *out_buf* with size *out_len*. The function returns actual length of the encoded chunk which may be smaller than *out_len*. If the output buffer is too small for the encoded data the failure flag will be set (see below).
- uint32* *C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
- streambuf** *C.get_src_stream()* returns the current source stream.
- void* *C.set_src_stream(streambuf * src_stream, bool own_stream = false)*
 sets the source stream (cf. constructor).
- void* *C.set_src_file(const char * file_name)*
 sets a file as source stream.
- streambuf** *C.get_tgt_stream()* returns the current target stream.
- void* *C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)*
 sets the target stream (cf. constructor).
- void* *C.set_tgt_file(const char * file_name)*
 sets a file as target stream.
- void* *C.reset(bool keep_parameters = true)*
 puts *C* in the same state as the default constructor. If *keep_parameters* is false the parameters are set to their default values.
- bool* *C.failed()* returns *true* if an error occured.
- bool* *C.finished()* returns *true* if the coding is finished.
- string* *C.get_description()* provides a description for *C*.

Additional Operations

- int* *C.get_compression_level()*
 returns the current compression level.

<i>void</i>	<i>C.set_compression_level(int level)</i>	sets the compression level (between 0 and 9), whereas 0 means no compression, 1 gives the best speed and 9 yields the highest compression.
<i>int</i>	<i>C.get_window_size()</i>	returns the base two logarithm of the size of the sliding window used by the deflation algorithm.
<i>void</i>	<i>C.set_window_size(int log2_of_sz)</i>	sets the window size (<i>log2_of_sz</i> must be between 8 and 15).
<i>int</i>	<i>C.get_memory_level()</i>	returns the current memory level.
<i>void</i>	<i>C.set_memory_level(int level)</i>	sets the memory level (between 1 and 9). The higher this number, the higher the memory consumption.
<i>int</i>	<i>C.get_strategy()</i>	returns the current strategy for the deflation algorithm.
<i>void</i>	<i>C.set_strategy(int strategy)</i>	sets the compression strategy (between 0 and 3): 0=default, 1=optimization for filtered data, i.e. small values with random distribution, 2=Huffman only (no string matching), 3=RLE (for image data).
<i>void</i>	<i>C.get_memory_consumption(uint32& mem_for_enc, uint32& mem_for_dec)</i>	returns the (approximate) memory consumption (in bytes) needed for encoding and decoding respectively.
<i>uint32</i>	<i>C.get_enc_buffer_size()</i>	returns the size of the buffer for encoded data.
<i>void</i>	<i>C.set_enc_buffer_size(uint32 buffer_size)</i>	sets the size of the buffer for encoded data.
<i>uint32</i>	<i>C.get_dec_buffer_size()</i>	returns the size of the buffer for decoded data.
<i>void</i>	<i>C.set_dec_buffer_size(uint32 buffer_size)</i>	sets the size of the buffer for decoded data.

10.5 Dictionary Based Coder (*DictCoder*)

1. Definition

The class *DictCoder* provides a dictionary based coder. The algorithms for encoding and decoding follow the ideas of Lempel and Ziv [93, 94].

```
#include < LEDA/coding/dict_coder.h >
```

2. Creation

```
DictCoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
            bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
DictCoder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).
<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.

<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

10.6 Static Huffman Coder (HuffmanCoder)

1. Definition

The class *HuffmanCoder* provides a static coder based on the algorithm by Huffman [48]. The term *static* means that a fixed model is used for encoding. The input is scanned twice. In the first scan the frequencies of the characters are counted. This information is used to precompute the Huffman-trees. The actual coding takes place in a second scan.

```
#include < LEDA/coding/huffman.h >
```

2. Creation

```
HuffmanCoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
                bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
HuffmanCoder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).
<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.

<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

10.7 Adaptive Huffman Coder (AdaptiveHuffman-Coder)

1. Definition

The class *AdaptiveHuffmanCoder* provides an adaptive coder based on the algorithm by J.S. Vitter [87]. Vitter has proven that his algorithm achieves the best compression among all one-pass Huffman schemes.

```
#include < LEDA/coding/huffman.h >
```

2. Creation

```
AdaptiveHuffmanCoder C(streambuf *src_stream = 0, streambuf *tgt_stream = 0,
                        bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
AdaptiveHuffmanCoder C(const char *src_file_name, const char *tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

```
void          C.encode()          encodes the source stream and writes the output to
                                the target stream.
```

```
void          C.decode()          decodes the source stream and writes the output to
                                the target stream.
```

```
uint32       C.encode_memory_chunk(const char *in_buf, uint32 in_len, char *out_buf,
                                    uint32 out_len)
                                encodes the memory chunk starting at in_buf with
                                size in_len into the buffer starting at out_buf with size
                                out_len. The function returns actual length of the
                                encoded chunk which may be smaller than out_len. If
                                the output buffer is too small for the encoded data
                                the failure flag will be set (see below).
```

```
uint32       C.decode_memory_chunk(const char *in_buf, uint32 in_len, char *out_buf,
                                    uint32 out_len)
                                decodes a memory chunk. The meaning of the pa-
                                rameters and the return value is the same as in the
                                previous function.
```

<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

10.8 Run-Length Coder (RLECoder)

1. Definition

A Run-Length coder is used for compressing inputs which contain many long sequences of repeating characters. The basic idea is as follows: A sequence *aaaaaaa* of 7 consecutive *a*'s is replaced by something like *a#7*.

We provide two schemes for the actual encoding of the compressed sequence, which allows the user to select between fast or high compression.

```
#include < LEDA/coding/RLE.h >
```

2. Creation

```
RLECoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
            bool own_streams = false, bool fast_mode = true);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*. The parameter *fast_mode* allows to select fast or high compression mode.

```
RLECoder C(const char * src_file_name, const char * tgt_file_name,
            bool fast_mode = true);
```

creates an instance *C* which uses file-streams for input and output. The parameter *fast_mode* allows to select fast or high compression mode.

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).

<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset(bool keep_mode = true)</i>	puts <i>C</i> in the same state as the default constructor. If <i>keep_mode</i> is false the compression mode is set to the default value.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

Additional Operations

<i>bool</i>	<i>C.is_in_fast_mode()</i>	returns <i>true</i> if the coder is in fast mode, and <i>false</i> if it is in high compression mode.
<i>void</i>	<i>C.set_fast_compression_mode()</i>	selects fast compression mode.
<i>void</i>	<i>C.set_high_compression_mode()</i>	selects high compression mode.

10.9 Burrows-Wheeler Transform (BWTCoder)

1. Definition

The class *BWTCoder* applies the Burrows-Wheeler transform [18] (in encoding mode) or its reversal (in decoding mode) to the input stream. To be more precise, in encoding mode the input stream is partitioned in blocks and the transformation is applied to each block. The size of the blocks, i.e. the number of characters per block, can be specified by the user.

This transformation does not compress the input but it can be used as a preprocessing step for other coders. Applying *BWTCoder* first often improves the overall compression rates. The following combinations yield very good compression results:

- CoderPipe3<BWTCoder, MTFCoder, AOCoder>
- CoderPipe4<BWTCoder, MTFCoder, RLEOCoder, AOCoder>

```
#include < LEDA/coding/BWT.h >
```

2. Creation

```
BWTCoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
            bool own_streams = false, uint32 block_size = DefaultBlockSize);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*. The block size can be controlled via *block_size*.

```
BWTCoder C(const char * src_file_name, const char * tgt_file_name,
            uint32 block_size = DefaultBlockSize);
```

creates an instance *C* which uses file-streams for input and output. The block size can be controlled via *block_size*.

3. Operations

Standard Operations

<i>void</i>	<i>C</i> .encode()	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C</i> .decode()	decodes the source stream and writes the output to the target stream.

<i>uint32</i>	<i>C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).
<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset(bool keep_block_size = true)</i>	puts <i>C</i> in the same state as the default constructor. If <i>keep_block_size</i> is false the block size is set to the default value.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

Additional Operations

<i>uint32</i>	<i>C.get_block_size()</i>	returns the current block size (for encoding).
<i>void</i>	<i>C.set_block_size(uint32 block_size)</i>	sets the block size.

4. Implementation

Our implementation is based on code for suffix sorting by P. Ferragina and G. Manzini.

10.10 Move-To-Front Coder (MTFCoder)

1. Definition

A Move-To-Front coder is used for preprocessing the input before it is fed to the actual compressor. Encoding works as follows: The coder maintains a list L containing all the 256 characters that can appear in the input. Whenever it receives an input character c it looks up the position i of c in L , outputs i and moves c to the front of L .

Let us look at an example. Assume that the position of every character in the initial list is equal to its ASCII-code. When we encode the sequence *aaabbbbaab* we obtain the output 97, 0, 0, 98, 0, 0, 0, 1, 0, 1. So a *MTFCoder* has the following properties:

- If the input contains sequences where one character is repeated many times then the output will have a lot of consecutive zeros.
- A sequence in the input where a small set of different characters is used corresponds to a sequence in the output with (mainly) small integers.

Therefore this coder is often used as an intermediate coding step between a Burrows-Wheeler transform (see Section 10.9) and a compressing coder.

```
#include < LEDA/coding/MTF.h >
```

2. Creation

```
MTFCoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
           bool own_streams = false);
```

creates an instance C which uses the given source and target streams. If *own_streams* is set, then C is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of C .

```
MTFCoder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance C which uses file-streams for input and output.

3. Operations

Standard Operations

```
void C.encode()
```

encodes the source stream and writes the output to the target stream.

```
void C.decode()
```

decodes the source stream and writes the output to the target stream.

- uint32* *C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 encodes the memory chunk starting at *in_buf* with size *in_len* into the buffer starting at *out_buf* with size *out_len*. The function returns actual length of the encoded chunk which may be smaller than *out_len*. If the output buffer is too small for the encoded data the failure flag will be set (see below).
- uint32* *C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
- streambuf** *C.get_src_stream()* returns the current source stream.
- void* *C.set_src_stream(streambuf * src_stream, bool own_stream = false)*
 sets the source stream (cf. constructor).
- void* *C.set_src_file(const char * file_name)*
 sets a file as source stream.
- streambuf** *C.get_tgt_stream()* returns the current target stream.
- void* *C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)*
 sets the target stream (cf. constructor).
- void* *C.set_tgt_file(const char * file_name)*
 sets a file as target stream.
- void* *C.reset()* puts *C* in exactly the same state as the default constructor.
- bool* *C.failed()* returns *true* if an error occurred.
- bool* *C.finished()* returns *true* if the coding is finished.
- string* *C.get_description()* provides a description for *C*.

10.11 Move-To-Front Coder II (MTF2Coder)

1. Definition

This is a variant of the Move-To-Front coder from the previous section. It was proposed by Balkenhol and Shtarkov [7] and sometimes yields better compression than *MTFCoder* (when used with *BWTCoder* as preprocessor and *A0Coder* as postprocessor). The idea is not to exchange the symbol at the head of MTF list *L* whenever a new symbol is encountered.

The details are as follows: Let us call the position of a symbol *c* in *L* the *rank* of *c* where the rank of the head symbol is 0. Whenever a symbol of rank greater than 1 appears we move it to position 1, i.e. behind the head. When a symbol of rank 1 is encountered it is moved to position 0 only if the previous symbol was not the head of *L*. Otherwise it remains at position 1.

```
#include < LEDA/coding/MTF2.h >
```

2. Creation

```
MTF2Coder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
            bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
MTF2Coder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).

<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

10.12 RLE for Runs of Zero (RLE0Coder)

1. Definition

The class *RLE0Coder* is designed for compressing inputs which contain many runs of the character *0x00*. This coder is useful as a preprocessing stage for a Move-To-Front coder. (This stage was suggested by D.J. Wheeler and described by P. Fenwick [32].)

The following combinations of coders often yield very good compression results:

- `CoderPipe4<BWTCoder, MTFCoder, RLE0Coder, A0Coder>`
- `CoderPipe4<BWTCoder, MTF2Coder, RLE0Coder, A0Coder>`

```
#include < LEDA/coding/RLE0.h >
```

2. Creation

```
RLE0Coder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
            bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
RLE0Coder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

<i>void</i>	<i>C</i> . <code>encode()</code>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C</i> . <code>decode()</code>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C</i> . <code>encode_memory_chunk(const char * <i>in_buf</i>, <i>uint32</i> <i>in_len</i>, char * <i>out_buf</i>, <i>uint32</i> <i>out_len</i>)</code>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).

<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

10.13 Checksummers (`checksummer_base`)

1. Definition

The class `checksummer_base` is the base class for all LEDA checksummers. It cannot be instantiated. In order to avoid repeating this documentation for each derived class below we will discuss its members here.

When a checksummer is used in encoding mode it can add checksums to the output stream. This is controlled by the `checksums_in_stream` flag. If this flag is set and the block size is zero (default setting) then one checksum is appended at the end of the stream. If the flag is switched on and the block size b is positive then a checksum is written for every block of b characters.

When the checksummer is used in decoding mode this flag specifies whether the source stream contains checksums. If so, they will be compared against the computed checksum for the stream (or for the respective block if the block size is positive).

If you use a checksummer in a coder pipe (cf. Section 10.23) then it should be the first coder in the pipe. This ensures that the checksum is computed for the original input. Finally, we want to point out that all checksummers provide fast seek operations (cf. Section 10.22).

```
#include < LEDA/coding/checksum.h >
```

2. Creation

```
checksummer_base C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
                  bool own_streams = false);
```

creates an instance C which uses the given source and target streams. If `own_streams` is set, then C is responsible for the destruction of the streams, otherwise the pointers `src_stream` and `tgt_stream` must be valid during the life-time of C .

```
checksummer_base C(const char * src_file_name, const char * tgt_file_name = 0);
```

creates an instance C which uses file-streams for input and output.

3. Operations

Standard Operations

```
void C.encode() encodes the source stream and writes the output to the target stream.
```

```
void C.decode() decodes the source stream and writes the output to the target stream.
```

- uint32* *C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 encodes the memory chunk starting at *in_buf* with size *in_len* into the buffer starting at *out_buf* with size *out_len*. The function returns actual length of the encoded chunk which may be smaller than *out_len*. If the output buffer is too small for the encoded data the failure flag will be set (see below).
- uint32* *C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
- streambuf** *C.get_src_stream()* returns the current source stream.
- void* *C.set_src_stream(streambuf * src_stream, bool own_stream = false)*
 sets the source stream (cf. constructor).
- void* *C.set_src_file(const char * file_name)*
 sets a file as source stream.
- streambuf** *C.get_tgt_stream()* returns the current target stream.
- void* *C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)*
 sets the target stream (cf. constructor).
- void* *C.set_tgt_file(const char * file_name)*
 sets a file as target stream.
- void* *C.reset(bool keep_parameters = true)*
 puts *C* in the same state as the default constructor. If *keep_parameters* is false the parameters are set to their default values.
- bool* *C.failed()* returns *true* if an error occured or a checksum in the stream does not match the computed checksum.
- bool* *C.finished()* returns *true* if the coding is finished.
- string* *C.get_description()* provides a description for *C*.

Additional Operations

- string* *C.check()* checks the source stream and returns the computed checksum. No target stream needs to be set. (If a target stream is set, **check** coincides with **decode**).

<i>bool</i>	<code>C.checksum_is_valid()</code>	returns whether <i>C</i> has a valid checksum.
<i>string</i>	<code>C.get_checksum_as_hex_string()</code>	returns the checksum for the stream that has been processed last as hexadecimal string.
<i>string</i>	<code>C.check(string str)</code>	computes a checksum for a string. (Sets source and target stream to <i>nil</i> .)
<i>void</i>	<code>C.set_checksums_in_stream_flag(bool sums_in_stream, uint32 blocksize = 0)</code>	sets the <i>checksums_in_stream</i> flag and the block size.
<i>bool</i>	<code>C.get_checksums_in_stream_flag()</code>	returns the <i>checksums_in_stream</i> flag.
<i>uint32</i>	<code>C.get_block_size()</code>	returns the current block size.

10.14 CRC32 Checksum (CRC32Coder)

1. Definition

The class *CRC32Coder* computes CRC32 checksums (see ISO 3309 and ITU-T V.42 for a formal specification).

```
#include < LEDA/coding/checksum.h >
```

10.15 CRC-CCITT Checksum (CCITTCoder)

1. Definition

The class *CCITTCoder* computes CRC-CCITT checksums (see ISO 3309).

```
#include < LEDA/coding/checksum.h >
```

10.16 Adler32 Checksum (Adler32Coder)

1. Definition

The class *Adler32Coder* computes Adler32 checksums (see RFC 1950, ZLIB specification version 3.3).

```
#include < LEDA/coding/checksum.h >
```

10.17 MD5 Checksum (MD5SumCoder)

1. Definition

The class *MD5SumCoder* computes MD5 checksums (see RFC 1321, The MD5 Message-Digest Algorithm).

```
#include < LEDA/coding/checksum.h >
```

10.18 SHA-1 Checksum (SHACoder)

1. Definition

The class *SHACoder* computes SHA-1 checksums (see FIPS PUB 180-1, Secure Hash Standard).

```
#include < LEDA/coding/checksum.h >
```

10.19 Encoding Output Stream (`encoding_ostream`)

1. Definition

The type `encoding_ostream<Coder>` is the encoding counterpart of the type `ostream` from the C++ iostream library. Each instance `os` of type `encoding_ostream<Coder>` is attached to a `streambuf sb`. Every data that is written to `os` is encoded on-the-fly by an instance of type `Coder` and then written to `sb`. All operations and all operators (<<) defined for C++ `ostreams` can be applied to `encoding_ostream` as well.

```
#include < LEDA/coding/coder_util.h >
```

2. Creation

```
encoding_ostream<Coder> os(streambuf * encoded_stream, bool own_stream = false);
```

creates an instance `os` and attaches it to the given `streambuf` object.

3. Operations

<code>Coder*</code>	<code>os.get_coder()</code>	returns the instance of <code>Coder</code> which is used for encoding.
<code>void</code>	<code>os.close()</code>	detaches <code>os</code> from its <code>streambuf</code> object.

10.20 Decoding Input Stream (`decoding_istream`)

1. Definition

The type `decoding_istream<Coder>` is the decoding counterpart of the type `istream` from the C++ iostream library. Each instance `is` of type `decoding_istream<Coder>` is attached to a `streambuf sb`. Whenever data is requested from `is`, it reads some data from `sb` and then decodes it on-the-fly with an instance of type `Coder`. All operations and all operators (>>) defined for C++ `istreams` can be applied to `decoding_istream` as well.

```
#include < LEDA/coding/coder_util.h >
```

2. Creation

```
decoding_istream<Coder> is(streambuf * encoded_stream, bool own_stream = false);
```

creates an instance `is` and attaches it to the given `streambuf` object.

3. Operations

<i>Coder*</i>	<i>is</i> .get_coder()	returns the instance of <i>Coder</i> which is used for encoding.
<i>void</i>	<i>is</i> .close()	detaches <i>is</i> from its <i>streambuf</i> object.
<i>void</i>	<i>is</i> .finish()	reads till the end of the stream and then closes <i>is</i> . (This is useful if <i>Coder</i> is a checksummer; the checksum is only verified after EOF has been read.)

10.21 Encoding File Stream (encoding_ofstream)

1. Definition

The type *encoding_ofstream*<*Coder*> is the encoding counterpart of the type *ofstream* from the C++ *iostream* library. Each instance *os* of type *encoding_ofstream*<*Coder*> is associated with a file. Every data that is written to *os* is encoded on-the-fly by an instance of type *Coder* and then written to the associated file. All operations and all operators (<<) defined for C++ *ostreams* can be applied to *encoding_ofstream* as well.

```
#include < LEDA/coding/coder_util.h >
```

2. Creation

```
encoding_ofstream<Coder> os(const char * file_name = 0, ios::openmode mode =
                           ios::openmode(ios::out | ios::trunc));
```

creates an instance *os*. If *file_name* is specified, the stream is attached to the file with the given name.

3. Operations

<i>bool</i>	<i>os</i> .is_open()	returns if <i>os</i> is attached to an open file.
<i>void</i>	<i>os</i> .open(const char * <i>file_name</i> = 0, ios::openmode <i>mode</i> = ios::openmode(ios::out ios::trunc))	opens a file and attaches <i>os</i> to it.
<i>void</i>	<i>os</i> .close()	closes the attached file and detaches <i>os</i> from it.
<i>streampos</i>	<i>os</i> .tellp()	queries the position of the (internal) put pointer. This pointer determines the position in the (original) stream whereto the next character is written.
<i>ostream&</i>	<i>os</i> .seekp(<i>streampos</i> <i>pos</i>)	sets the position of the put pointer to <i>pos</i> . <i>pos</i> must be greater than the current put pointer. The skipped characters are assumed to be zero.

<i>ostream&</i>	<i>os.seekp(streamoff off, ios::seekdir dir)</i>	moves the put pointer by <i>off</i> relative to the position determined by <i>dir</i> . <i>dir</i> can be <i>ios::beg</i> (beginning), <i>ios::cur</i> (current position) or <i>ios::end</i> (last position). The new position of the put pointer has to be greater than its current position. The skipped characters are assumed to be zero.
<i>Coder*</i>	<i>os.get_coder()</i>	returns the instance of <i>Coder</i> which is used for encoding.

10.22 Decoding File Stream (*decoding_ifstream*)

1. Definition

The type *decoding_ifstream<Coder>* is the decoding counterpart of the type *ifstream* from the C++ *iostream* library. Each instance *is* of type *decoding_ifstream<Coder>* is associated with a file. Whenever data is requested from an instance *is* of type *decoding_ifstream<Coder>*, *is* reads some data from the associated file and then decodes it on-the-fly with an instance of type *Coder*. All operations and all operators (>>) defined for C++ *istreams* can be applied to *decoding_ifstream* as well.

decoding_ifstream supports random access read operations by providing seek operations. For this purpose it maintains a so-called *get pointer*. This pointer specifies the position in the decoded data stream from which the next read operation will extract its data. After the operation the get pointer refers to the position immediately behind the last extracted character. E.g., if you are not interested in the first 5000 characters and you want to extract the 10 characters in positions 5000 – 5009, you can perform a seek operation which moves the get pointer to position 5000 and then read 10 characters. (After that the get pointer will refer to position 5010.) This seek operation will usually be faster than skipping 5000 characters by hand.

Seek operations are supported no matter which coder is plugged into *decoding_ifstream*. However, some coders (like checksummers) provide fast seek operations. This manual mentions these coders explicitly. Moreover, we provide a class called *BlockCoder* (in Section 10.25) which allows you to speed up seeks for any coder.

```
#include <LEDA/coding/coder_util.h >
```

2. Creation

```
decoding_ifstream<Coder> is(const char * file_name = 0,  
ios::openmode mode = ios::in);
```

creates an instance *is*. If *file_name* is specified, the stream is attached to the file with the given name.

3. Operations

<i>bool</i>	<i>is.is_open()</i>	returns if <i>is</i> is attached to an open file.
<i>void</i>	<i>is.open(const char *file_name = 0, ios::openmode mode = ios::in)</i>	opens a file and attaches <i>is</i> to it.
<i>void</i>	<i>is.close()</i>	closes the attached file and detaches <i>is</i> from it.
<i>void</i>	<i>is.finish()</i>	reads till the end of the stream and then closes <i>is</i> . (This is useful if <i>Coder</i> is a checksummer; the checksum is only verified after EOF has been read.)
<i>streampos</i>	<i>is.tellg()</i>	queries the position of the (internal) get pointer. This pointer determines the position in the (decoded) stream from which the next character is read.
<i>istream&</i>	<i>is.seekg(streampos pos)</i>	sets the position of the get pointer to <i>pos</i> .
<i>istream&</i>	<i>is.seekg(streamoff off, ios::seekdir dir)</i>	moves the get pointer by <i>off</i> relative to the position determined by <i>dir</i> . <i>dir</i> can be <i>ios::beg</i> (beginning), <i>ios::cur</i> (current position) or <i>ios::end</i> (last position).
<i>Coder*</i>	<i>is.get_coder()</i>	returns the instance of <i>Coder</i> which is used for decoding.

10.23 Coder Pipes (CoderPipe2)

1. Definition

The type *CoderPipe2*< *Coder1*, *Coder2* > can be used to combine two coders of type *Coder1* and *Coder2* into one single coder. This works in an analogous way as a pipe of the operating system: In encoding mode the original input is processed by *Coder1*. Its output is fed into *Coder2*. The output of *Coder2* becomes the output of the pipe. In decoding mode the situation is reversed: The data is sent through *Coder2* first and then through *Coder1*.

We also provide pipes for combining more than two coders (up to six): *CoderPipe3*, ..., *CoderPipe6*. (Since these classes have a similar interface as *CoderPipe2*, we do not include manual pages for them.)

```
#include < LEDA/coding/coder_util.h >
```

2. Types

```
CoderPipe2< Coder1, Coder2 >::coder1
    the type Coder1.
```

```
CoderPipe2< Coder1, Coder2 >::coder2
    the type Coder2.
```

3. Creation

```
CoderPipe2< Coder1, Coder2 > C(streambuf * src_stream = 0,
    streambuf * tgt_stream = 0,
    bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
CoderPipe2< Coder1, Coder2 > C(const char * src_file_name,
    const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

4. Operations

Standard Operations

```
void          C.encode()      encodes the source stream and writes the output to
                                the target stream.
```

```
void          C.decode()     decodes the source stream and writes the output to
                                the target stream.
```

- uint32* *C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 encodes the memory chunk starting at *in_buf* with size *in_len* into the buffer starting at *out_buf* with size *out_len*. The function returns actual length of the encoded chunk which may be smaller than *out_len*. If the output buffer is too small for the encoded data the failure flag will be set (see below).
- uint32* *C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
- streambuf** *C.get_src_stream()* returns the current source stream.
- void* *C.set_src_stream(streambuf * src_stream, bool own_stream = false)*
 sets the source stream (cf. constructor).
- void* *C.set_src_file(const char * file_name)*
 sets a file as source stream.
- streambuf** *C.get_tgt_stream()* returns the current target stream.
- void* *C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)*
 sets the target stream (cf. constructor).
- void* *C.set_tgt_file(const char * file_name)*
 sets a file as target stream.
- void* *C.reset(bool keep_parameters = true)*
 puts *C* in the same state as the default constructor. If *keep_parameters* is false the parameters of all coders in the pipe are set to their default values.
- bool* *C.failed()* returns *true* if an error occurred or a checksum in the stream does not match the computed checksum.
- bool* *C.finished()* returns *true* if the coding is finished.
- string* *C.get_description()* provides a description for *C*.

Additional Operations

- Coder1** *C.get_coder1()* returns the currently used instance of *Coder1*.

- void* *C.set_coder1(Coder1 * c1, bool own_coder = false)*
 sets the instance of *Coder1*. If *own_coder* is *true*, then the *c1* is deleted by *C*. Otherwise *c1* is not deleted by *C* and the pointer *c1* must be valid during the life-time of *C*.
- Coder2** *C.get_coder2()* returns the currently used instance of *Coder2*.
- void* *C.set_coder2(Coder2 * c2, bool own_coder = false)*
 sets the instance of *Coder2*. The parameter *own_coder* is explained above.

10.24 Automatic Decoder (AutoDecoder)

1. Definition

An instance *C* of *AutoDecoder* can be used for decoding any stream that has been encoded with a LEDA coder or a pipe of LEDA coders. Thus this class is useful if you want to decode a stream and have forgotten which combination of coders you have used to encode it. This class is also helpful if the encoding method is not known at compile-time. Then the decoding method cannot be fixed at compile-time either but it has to be determined at run-time.

```
#include < LEDA/coding/auto_decoder.h >
```

2. Types

In order to facilitate the usage of *AutoDecoder* with *decoding_istream* we provide the typedef *autodecoding_istream* as a shorthand for *decoding_istream<AutoDecoder>*.

3. Creation

```
AutoDecoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
              bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
AutoDecoder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

4. Operations

Standard Operations

```
void          C.decode()          decodes the source stream and writes the output to
                                the target stream.
```

```
streambuf*   C.get_src_stream()  returns the current source stream.
```

```
uint32       C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf,
                                uint32 out_len)
```

decodes the memory chunk starting at *in_buf* with size *in_len* into the buffer starting at *out_buf* with size *out_len*. The function returns actual length of the encoded chunk which may be smaller than *out_len*. If the output buffer is too small for the decoded data the failure flag will be set (see below).

<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if decoding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> . After decoding this includes a description of the coder that has been used for encoding the stream.

Additional Operations

<i>coder_base*</i>	<i>C.get_coder()</i>	after decoding this function returns the coder that has actually been used to decode the stream. E.g., if the original source stream has been encoded with an instance of type <i>A0Coder</i> then the function returns an instance of <i>A0Coder</i> .
--------------------	----------------------	---

10.25 Block Coder (BlockCoder)

1. Definition

An instance of type *BlockCoder*<*Coder*> encodes a source stream as follows: It divides the stream into equally sized blocks and encodes each block separately with an instance of type *Coder*. If you later want to decode only parts of the encoded data then you do not have to decode the entire data but only the appropriate blocks, which is usually much faster. (The block size can be specified by the user; please note that the main memory of your computer has to be large enough to hold one block.)

The class *BlockCoder* has been designed to speed up the seek operations of the class *decoding_ifstream*<*Coder*> (see Section 10.22). In order to gain the speed up simply replace the template parameter *Coder* in *decoding_ifstream* by *BlockCoder*<*Coder*> (see also the example below).

There is an important precondition for *BlockCoder*: In encoding mode the target stream must support seek operations which query the current position (i.e. *seek*(0, *ios::cur*, *ios::out*)). In decoding mode the source stream must be capable of random seek operations.

These conditions are surely fulfilled if the respective stream is a file. Moreover, if *BlockCoder* is used within a coder pipe the pipe will make sure that it operates properly. However, this configuration only makes sense if all coders in the pipe optimize seek operations. Then the whole pipe will offer fast seek operations.

```
#include < LEDA/coding/block_coder.h >
```

2. Creation

```
BlockCoder<Coder> C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,  
                 bool own_streams = false,  
                 wint32 block_size = DefaultBlockSize);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*. The initial block size is *block_size*.

```
BlockCoder<Coder> C(const char * src_file_name, const char * tgt_file_name,  
                 wint32 block_size = DefaultBlockSize);
```

creates an instance *C* which uses file-streams for input and output. The block size is set to *block_size*.

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below).
<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset(bool keep_block_size = true)</i>	puts <i>C</i> in the same state as the default constructor. If <i>keep_block_size</i> is false, the block size is set to the default value.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.

```
string out_file1 = tmp_file_name(), out_file2 = tmp_file_name();

Coder c1(in_file, out_file1);
c1.encode(); c1.reset();
cout << "encoded size: " << size_of_file(out_file1) << endl;
autodecoding_ifstream is1(out_file1);
test_random_seek(is1); is1.close();
// output on my machine: enc. sz: 2201723 / Timer(seek): 51.36 s

BlockCoder<Coder> c2(in_file, out_file2);
c2.encode(); c2.reset();
cout << "encoded size: " << size_of_file(out_file2) << endl;
autodecoding_ifstream is2(out_file2);
test_random_seek(is2); is2.close();
// output on my machine: enc. sz: 2207892 / Timer(seek): 1.91 s

delete_file(out_file1); delete_file(out_file2); return 0;
}
```

10.26 Memory Streambuffer (`memory_streambuf`)

1. Definition

An object *mb* of the class *memory_streambuf* can be used as source or target stream for a coder and allows encoding and decoding in memory (i.e. without file accesses). Every read or write operation is forwarded to a buffer in memory. This buffer is directly accessible by the user. The length of this buffer is called the *capacity* of *mb*. The *size* of *mb* is the number of characters that can be read from or written to the stream before an underflow/overflow occurs. (In that case the corresponding stream operation returns EOF (end-of-file).) Thus the capacity is the maximum size that *mb* can have without reallocating its buffer.

```
#include < LEDA/coding/memory_streambuf.h >
```

2. Creation

```
memory_streambuf mb(streamsize buf_sz = 0, bool wipe_buf = false);
```

creates an object *mb* with capacity and size *buf_sz*. The parameter *wipe_buf* determines whether *wipe_buffer* is called when the buffer is not needed any more.

```
memory_streambuf mb(char * buf, streamsize buf_sz, bool own_buf = false,  
                    bool wipe_buf = false);
```

creates an object *mb* with the memory buffer *buf* and sets the capacity and the size to *buf_sz*. If *own_buf/wipe_buf* is true, then *buf* is deleted/wiped by *mb* when it is not used anymore. Note that *buf* is not copied but it is used as the internal buffer of *mb*.

3. Operations

```
void          mb.reset()
```

moves the internal get and put pointers to the beginning of the buffer and clears the underflow/overflow flags.

```
streamsize   mb.get_capacity()
```

returns the current capacity.

```
streamsize   mb.get_size()
```

returns the current size.

```
void          mb.set_size(streamsize n)
```

changes the size to *n* and calls *reset*. (If *n* exceeds the capacity then a new buffer with sufficient capacity is allocated. The contents of the old buffer are not copied.)

<i>void</i>	<i>mb.truncate(streamsize n)</i>	also changes the size to <i>n</i> , but never allocates a new buffer. <i>Precondition: n ≤ current capacity.</i>
<i>char*</i>	<i>mb.get_buffer()</i>	returns the memory buffer of <i>mb</i> .
<i>void</i>	<i>mb.set_buffer(char * buf, streamsize buf_sz, bool own_buf = false, bool wipe_buf = false)</i>	makes <i>buf</i> the new memory buffer and changes capacity and size to <i>buf_sz</i> . (The meaning of <i>own_buf</i> and <i>wipe_buf</i> is the same as in the second constructor.)
<i>void</i>	<i>mb.wipe_buffer()</i>	like <i>reset</i> , in addition all bytes in the memory buffer are set to zero.
<i>streamsize</i>	<i>mb.in_avail()</i>	returns how many characters can be read from <i>mb</i> before an underflow occurs.
<i>streamsize</i>	<i>mb.in_count()</i>	returns how many characters have been read from <i>mb</i> since the last <i>reset</i> .
<i>streamsize</i>	<i>mb.out_avail()</i>	returns how many characters can be written to <i>mb</i> before an overflow occurs.
<i>streamsize</i>	<i>mb.out_count()</i>	returns how many characters have been written to <i>mb</i> since the last <i>reset</i> .
<i>bool</i>	<i>mb.had_underflow()</i>	returns whether an underflow has occurred since the last <i>reset</i> .
<i>bool</i>	<i>mb.had_overflow()</i>	returns whether an overflow has occurred since the last <i>reset</i> .

Chapter 11

Symmetric Key Cryptography

LEDA covers the following aspects of symmetric key cryptography:

- encryption (= enciphering) and decryption (= deciphering) of a stream:
Encryption takes as input some *plaintext* (a stream of data) and a *key* (a small piece of secret data) and outputs some *ciphertext*. *Decryption* is the reverse operation: its input consists of the ciphertext and a key, and its output is the original plaintext. The idea is that the plaintext cannot be recovered from the ciphertext without knowing the correct decryption key. This property is called *secrecy*. It allows you to send the ciphertext through an insecure channel or to store it on an insecure filesystem. There are algorithms where the decryption key differs from the corresponding encryption key. An algorithm which uses the same key for both operations is called *symmetric*. (All algorithms provided by LEDA have this property.)
- authentication of a stream:
Authentication takes as input a message and a key and outputs a so-called *Message Authentication Code* (MAC). A MAC can be seen as a key-dependent checksum. The idea is that nobody can generate a valid MAC for a message without knowing the key. So if message and MAC are sent through an insecure channel then the receiver – given that he knows the key – can verify that the text has not been tampered with (*integrity*) and that it originates from someone knowing the key (*authentication*). MACs are also useful if you want to make sure that no intruder (in particular no virus) can alter a file on your system. (If ordinary checksums were used the intruder could change the file and then simply update corresponding checksum.)
- key generation:
The security of a cryptographic system depends heavily on the strength of its keys. If an attacker can obtain your keys he can decrypt your messages or fake MACs no matter how good the encryption and authentication algorithms are. In order to support the user LEDA provides secure methods to generate a key from a human-readable passphrase. Of course, the user has the responsibility to choose a good passphrase, i.e. a phrase that cannot be guessed easily by an attacker.

All these topics will be discussed in detail later. We want to point out that secrecy and authentication are two orthogonal concepts. If you use only authentication, nobody will

be able to change your message without being detected but everybody can read it. On the other hand, if you use only encryption then nobody can read your message but an attacker could change it. At first sight this does not seem to make much sense because the attacker can only alter ciphertext and he will not be able to predict what the corresponding plaintext will look like. However, this may still cause damage. Imagine for example a satellite that is remote controlled via encrypted but unauthenticated commands. If an attacker manages to make the satellite listen to his commands, he cannot exploit the device but he might be able to make it leave its orbit and crash.

Hence, sometimes secrecy and authentication must be used together to achieve the desired security. LEDA makes it easy to combine these different aspects. The example below will illustrate this. The program is similar to the opening example of Chapter Compression. It consists of three parts: key generation, encoding and decoding. Each part will be explained below.

```
#include <LEDA/coding/crypt.h> // contains all cryptography classes

using namespace leda;

void generate_keys(CryptKey& auth_key, CryptKey& cipher_key)
{
    // key generation (two keys)
    CryptByteString passphrase = CryptKey::read_passphrase("Passphrase: ");
    CryptByteString salt(1);
    salt[0] = 'a'; // for authentication
    auth_key = CryptKey::generate_key(128/8, passphrase, salt);
    salt[0] = 'c'; // for enciphering/deciphering
    cipher_key = CryptKey::generate_key(128/8, passphrase, salt);
}

int main()
{
    string str = "Hello World";
    CryptKey auth_key, cipher_key;

    // encode: MAC -> compress -> encipher
    typedef CoderPipe3< OMACCoder<>, PPMIICoder, CBCCoder<> > CryptCoder;
    encoding_ofstream<CryptCoder> out("foo");
    generate_keys(auth_key, cipher_key);
    out.get_coder()->get_coder1()->set_key(auth_key);
    out.get_coder()->get_coder3()->set_key(cipher_key);
    out << str << "\n";
    out.close();
    if (out.fail()) std::cout << "error writing foo" << "\n";

    // decode: decipher -> decompress -> MAC
    decoding_ifstream<CryptCoder> in("foo");
    generate_keys(auth_key, cipher_key);
}
```

```

in.get_coder()->get_coder1()->set_key(auth_key);
in.get_coder()->get_coder3()->set_key(cipher_key);
str.read_line(in);
in.finish(); // read till EOF is reached and then close "in"
if (in.fail()) std::cout << "error authenticating foo" << "\n";

std::cout << "decoded string: " << str << "\n";

return 0;
}

```

In the first part of the program (function *generate_keys*) two keys are generated. The input for each generation is a passphrase and a salt. The passphrase is a human-readable and easy-to-remember string which must be kept secret. The salt is an array of bytes (in the example just one byte) which should be unique but it can be made public without endangering security. It allows to generate different keys from a single passphrase. In the example we generate one key for authentication and one key for encryption. More information on key generation can be found in Section *CryptKey*.

In the second part (beginning of *main*) we encode a message. We use a coder pipe *CryptCoder* which first authenticates (*OMACCoder*), then compresses (*PPMIICoder*) and finally encrypts (*CBCCoder*) its source stream. Observe that the output of the *OMACCoder* (in encoding mode) is the original input plus the MAC for this input. (In decoding mode this MAC will be verified automatically.) In order to use the *CryptCoder* we construct an *encoding_ofstream* called *out*. After setting the keys of the cryptographic coders we can use *out* just like an ordinary *ofstream*.

We want to point out that the order of the coders in the pipe is not arbitrary. It makes sense to put the authentication at the very beginning because you want to authenticate the original plaintext and not some compressed or encrypted version of it. Moreover, it is important to place compression *before* encryption for two reasons: Since compression usually destroys patterns and structures in the plaintext it can be seen as a way of obscuring the plaintext, which can be a helpful preprocessing step for encryption. But the following is even more important: As encryption transforms its input into a seemingly random stream applying compression after encryption usually increases the length of stream. (Some cryptographers even warn not to trust an encryption algorithm if its output can be compressed well [80].)

Now we describe the decoding process (at the end of *main*). It looks very similar to the encoding process but instead of *encoding_ofstream* we use its counterpart *decoding_ifstream*. After the key set up the stream *in* can be used as a usual C++ input stream. However, there is one subtle point that we want to highlight: When we are done with *in* we do not call the *close* but the *finish* method. This reads the stream till its end before closing it. This ensures that the *OMACCoder* verifies the MAC and reports an error if the computed MAC and the MAC found in the stream differ. (If *in* were closed before its end is reached then no authentication would be performed and no error would be signaled. The reader is invited to try this out.)

We want to discuss a feature of LEDA that can simplify the decoding process. Suppose a friend of yours has sent you an authenticated and encrypted file over the internet, and he has provided you the authentication and the encryption key (via a secure channel). But

unfortunately he did not tell you which coders he actually used for encoding his message. Then you can use the *CryptAutoDecoder* to decode his message. This class is able to automatically reconstruct the coder (or the coder pipe) that was used for encoding the stream:

```
decoding_ifstream<CryptAutoDecoder> in("foo");
in.get_coder()->add_key(auth_key);
in.get_coder()->add_key(cipher_key);
```

Of course, LEDA also supports encryption and decryption of files:

```
// encryption
CoderPipe3< OMACCoder<>, PPMIICoder, CBCCoder<> > coder;
coder.set_src_file("input.txt"); coder.set_tgt_file("output");
coder.get_coder1()->set_key(auth_key);
coder.get_coder3()->set_key(cipher_key);
coder.encode();

// decryption
CryptAutoDecoder auto("output", "input.txt");
auto->add_key(auth_key); auto->add_key(cipher_key);
auto.decode();
```

We want to discuss some security assumptions made by LEDA, i.e. some preconditions that must be fulfilled in order to ensure the security of your data:

- Your passphrases and your keys must be safe. That means that the user is responsible for choosing passphrases that cannot be guessed easily by an attacker. One way to “generate” such a passphrase is to take a sentence and to deliberately add some typos like “LEDA’s cryptographic algorithms are very good!”. (If you get tired of such long phrases you could use a phrase that consists basically of the first letter of every word: “L’scaa++!”) If passphrases or keys are stored on a disc this disc must be protected against an attacker. (Also take care of temporary copies, they must be thoroughly wiped out. Simply deleting a file does not suffice because its contents can still be recovered with certain tools. Some specialists are even capable of recovering data on a hard disc that has been overwritten once.)
- The main memory of your computer must be safe. While cryptographic operations are performed passphrases and keys are stored in plaintext in the main memory of the computer. Therefore the user must make sure that no attacker can inspect any memory used by his process (in particular while the process is running). Some features of LEDA support the user in making this kind of attack harder: The class *CryptByteString* and the derived class *CryptKey* overwrite their memory before they free it and return it to the system. We want to point out that this precaution can be foiled by the operating system. If it swaps some security sensitive part of the memory to a swap file on a hard disc then this data may remain there after the termination of your process. (On some platforms LEDA prevents this swapping, see Section *CryptKey*.)

We want to address another important issue. Some readers might be worried about the fact that a potential attacker can purchase a copy of the source code of LEDA. One may wonder if this is a security risk. Fortunately, this is not the case. The cryptographic algorithms in LEDA have been designed under the assumption that a potential attacker knows the algorithm (but not the key). All the algorithms have appeared in scientific publications and successfully passed thorough cryptographic analysis. The fact that the source code can be purchased allows you to verify that the developers of LEDA did not put any trap-doors into the code which allow them to decrypt data without knowing the key. (This means: If you loose your passphrase or your key then we are not able to help you to recover your encrypted data.)

11.1 Secure Byte String (CryptByteString)

1. Definition

An instance s of the class *CryptByteString* is basically a string of bytes. When s is not used anymore its memory is wiped out (by overwriting it a couple of times) before the memory is freed and returned to the system. The goal is to prevent an attacker from reading security sensitive data after your process has terminated. We want to point out that this mechanism can be foiled by the operating system: If it swaps the memory occupied by s to a swap file on a hard disc then the data will not be erased by s . (Some platforms offer to lock certain parts of the memory against swapping. *CryptByteString* uses this feature on Windows NT/2000/XP to protect its memory.)

As we have stated above s can be used like a string or an array of bytes. The *size* n of s is the number of bytes in s , they are indexed from 0 to $n - 1$.

Important: If you create a *CryptByteString* s from a C-style array or a string, or if you convert s to a *string*, then only the memory of s will be wiped out but not the memory of the array or the string.

```
#include < LEDA/coding/crypt_key.h >
```

2. Creation

CryptByteString s ; creates an empty string.

CryptByteString s (*uint16* *size*);
creates a string of the given *size*. All bytes in s are set to zero.

CryptByteString s (*const byte * bytes*, *uint16 num_bytes*);
creates a copy of the array *bytes* of size *num_bytes*.

CryptByteString s (*const char * str*);
creates a copy of the C-style string *str*. (The '\0' character at the end is not copied.)

3. Operations

<i>uint16</i>	$s.get_size()$	returns the size of s .
<i>bool</i>	$s.is_empty()$	returns true iff s is empty.
<i>void</i>	$s.clear()$	makes s the empty string.
<i>const byte*</i>	$s.get_bytes()$	returns the internal byte-array of s .
<i>byte&</i>	$s[uint16\ idx]$	returns the byte at position <i>idx</i> . <i>Precondition:</i> $0 \leq idx \leq s.get_size() - 1$.

<i>CryptByteString</i>	<i>s</i> (<i>uint16 idx_start</i> , <i>uint16 idx_end</i>)	returns the substring <i>s</i> [<i>idx_start</i>], . . . , <i>s</i> [<i>idx_end</i>].
<i>CryptByteString</i>	<i>s</i> .hash(<i>uint16 num_iterations</i> = 1)	computes a hash of <i>s</i> , <i>num_iterations</i> specifies how often the hash function is applied.
<i>string</i>	<i>s</i> .to_hex_string()	computes a hexadecimal representation of <i>s</i> , each byte is represented by two hex-digits.
<i>string</i>	<i>s</i> .to_string()	converts <i>s</i> into a <i>string</i> .
<i>CryptByteString</i>	<i>const CryptByteString& x</i> + <i>const CryptByteString& y</i>	returns the concatenation of <i>x</i> and <i>y</i> .
<i>CryptByteString</i>	<i>CryptByteString::from_hex_string(const char * hex_str)</i>	creates a <i>CryptByteString</i> from a string of hex-digits.
<i>CryptByteString</i>	<i>CryptByteString::from_string(const char * str)</i>	converts the string <i>str</i> into a <i>CryptByteString</i> .
<i>void</i>	<i>CryptByteString::wipe_memory(void * mem, uint32 sz)</i>	wipes out <i>sz</i> bytes starting at the address given by <i>mem</i> .

11.2 Key for Cryptography (CryptKey)

1. Definition

Instances of the class *CryptKey* store keys for cryptographic algorithms. *CryptKey* is derived from *CryptByteString* and hence, its instances also wipe out their memory upon destruction. Apart from the operations of its base class *CryptKey* provides some static operations which can be helpful for key generation.

```
#include < LEDA/coding/crypt_key.h >
```

2. Creation

CryptKey *k*; creates an empty key.

CryptKey *k*(*uint16 size*);
 creates a key of the given *size*. All bytes in *k* are set to zero.

CryptKey *k*(*const byte * bytes*, *uint16 num_key_bytes*);
 initializes *k* with a copy of the array *bytes* of size *num_bytes*.

CryptKey *k*(*const CryptByteString& byte_str*);
 initializes *k* with *byte_str*.

CryptKey *k*(*const char * hex_str*);
 initializes *k* with the hexadecimal representation in *hex_str*.

Key generation

A key generation algorithm takes as input a (partially) secret seed *s* of arbitrary length and outputs a key *k* of the desired size. The gist of this process is to apply a secure hash function *H* to the seed and to use the returned hash value as the key, i.e. $k = H(s)$. In our implementation we use the checksum of the *SHACoder*, which is 20 bytes long. Since we want to be able to generate a key of size $n \neq 20$ we use the following approach: We divide the key into $p = \lceil n/20 \rceil$ portions k_1, \dots, k_p , where the size of k_1, \dots, k_{p-1} is 20 and the size of k_p is at most 20. We set $k_i = H(s \circ n \circ i)$. (Here “ $x \circ y$ ” denotes the concatenation of *x* and *y*, and k_p is possibly a proper suffix of the returned hash value.) Then we have $k = k_1 \circ \dots \circ k_p$.

The question is now what to use as seed for the key generation. The first idea that comes to mind is to use the passphrase supplied by the user. In that case the process would be vulnerable to the so-called dictionary attack. This works as follows: Since many users tend to choose their passphrases carelessly, the attacker builds a dictionary of common phrases and their corresponding keys. This gives him a set of “likely” keys which he tries first to break the system. One way to make this attack harder is to apply the hash function several times, i.e. instead of $k = H(s)$ we set $k = H(H(\dots H(s)))$. Even if we apply *H* some thousand times it does not slow down the generation of a single key noticeably. However, it should slow the generation of a whole dictionary considerably.

An even more effective counter measure is to use something that is called *salt*. This is a string which is appended to the passphrase to form the actual seed for the key generation. The salt does not have to be kept secret, the important point is that each key generation uses a different salt. So it is impossible to reuse a dictionary built for a specific salt. The salt is also useful if you want to reuse a passphrase. E.g., if you want to authenticate and to encrypt a file you might refrain from remembering two different phrases. But since it is not a good idea to use the same key twice you could generate two different keys by using two different salts.

CryptKey *CryptKey::generate_key*(*uint16 key_size*,
const CryptByteString& seed,
uint32 num_iterations)
 generates a key of size *key_size* by applying a hash function *num_iterations* times to the given *seed*.

- CryptKey* *CryptKey::generate_key*(*uint16 key_size*,
 const CryptByteString& passphrase,
 const CryptByteString& salt =
 CryptByteString(),
 uint32 num_iterations = 4096)
 generates a key from a *passphrase* and a *salt*. The seed for the generation is simply *passphrase* ◦ *salt*.
- CryptByteString* *CryptKey::generate_salt*(*uint16 salt_size*)
 generates a salt as follows: If *salt_size* is at least *sizeof(date)+4* then a representation of the current date is stored in the last *sizeof(date)* bytes of the salt. The remaining bytes are filled with pseudo-random numbers from a generator which is initialized with the current time.
- CryptKey* *CryptKey::generate_key_and_salt*(*uint16 key_size*, *uint16 salt_size*,
 const CryptByteString& passphrase,
 CryptByteString& salt,
 uint32 num_iterations = 4096)
 first some *salt* is generated (see above); then a key is generated from this *salt* and the given *passphrase*.
- CryptByteString* *CryptKey::read_passphrase*(*const string& prompt*,
 uint16 min_length = 6)
 writes the *prompt* to *stdout* and then reads a passphrase from *stdin* until a phrase with the specified minimum length is entered. (While the phrase is read *stdin* is put into unbuffered mode.)

11.3 Encryption and Decryption with Ciphers

A *stream-cipher* is a coder that encrypts or decrypts streams of data. An example for such a coder is the class *CBCCoder* that we have already seen in the sample program at the beginning of this chapter. Every stream-cipher in LEDA uses a block-cipher as building block. A *block-cipher* operates on “small” fixed-size blocks of plaintext or ciphertext – usually 64 or 128 bits. Mathematically, a block-cipher can be seen as pair of two functions E_K and D_K that depend on a key K . E_K takes as input a block B of size b and returns the encrypted block (also of size b), D_K describes the decryption operation. We have $D_K(E_K(B)) = B$ for all blocks B of size b and every admissible key K .

A stream-cipher is usually built by combining a block-cipher and some sort of feedback via some simple operations. The most simple stream-cipher is the *electronic codebook* (ECB) mode: No chaining is used. The plaintext is partitioned into n blocks P_1, \dots, P_n of size b . (If the last block P_n is shorter than b it is padded appropriately.) The ciphertext blocks C_1, \dots, C_n are obtained by applying the block-cipher to each block of the plaintext. More formally, $C_i = E_K(P_i)$. Decryption is simple, too: $P_i = D_K(C_i)$. This simplicity has an important drawback: If a block B appears several times in the plaintext each occurrence encrypts to the same ciphertext block. This can be exploited by an attacker: Suppose that the attacker knows P_1 (maybe because every plaintext starts with a fixed header) then he is able to detect every occurrence of P_1 in the plaintext without knowing the key!

To overcome this serious drawback stream-ciphers with feedback have been invented. They hide patterns in the plaintext in the ciphertext. In *cipher block chaining* (CBC) mode the current plaintext block is XORed with the previous ciphertext block (as feedback) before encryption. In short, $C_i = E_K(P_i \oplus C_{i-1})$. And decryption works as follows: $P_i = D_K(C_i) \oplus C_{i-1}$. In order to compute C_1 we need a so-called initialization vector (IV) C_0 . The IV does not have to be secret but it should be unique for every plaintext stream that is encrypted with a particular key K . The reason is the following: If you encrypt two streams with the same key and the same IV they will encrypt to same ciphertext up to the first position where the two plaintexts differ.

Another feedback mode is the *cipher feedback* (CFB) mode. It also uses an initialization vector C_0 . Encryption and decryption work as follows: $C_i = P_i \oplus E_K(C_{i-1})$ and $P_i = C_i \oplus E_K(C_{i-1})$. (Observe that the block-cipher is only used in encryption mode.) The IV for CFB **must** be unique (for CBC it **should** be unique), otherwise a cryptanalyst can recover the plaintext (see [80, Chapter 9.6]).

Finally, we want to describe the *output feedback* (OFB) mode. It computes a feedback stream S_0, S_1, \dots, S_n , where S_0 is an IV that should be unique. Despite the name of this mode, the feedback stream is completely internal it depends neither on the plaintext nor on the ciphertext: $S_i = E_K(S_{i-1})$. This mode looks as follows: $C_i = P_i \oplus S_i$ and $P_i = C_i \oplus S_i$.

Let us compare the four stream-ciphers from above. In terms of efficiency they are almost identical. The number of ciphertext blocks equals the number of plaintext blocks (not counting the IV). ECB is the fastest mode but the total running time is dominated by the time consumed by the block-cipher, the XOR operations used in the other modes are negligible. With respect to fault tolerance OFB is the best: One bit error in the ciphertext affects only one bit in the decrypted plaintext. In ECB mode one bit in the ciphertext affects the complete corresponding plaintext block. For CBC it affects the full

corresponding block in the plaintext and one bit in the next block. And in CFB mode the corresponding bit in the plaintext is affected as well as the complete next block. As to security ECB is clearly the worst because patterns in the plaintext are not hidden. The other three modes hide these patterns and they are almost comparable in terms of security. CBC has some small advantages (cf. [80, Chapter 9.11]). So if your are in doubt use CBC as stream-cipher.

The following table summarizes some facts about the stream-ciphers in LEDA:

mode	encryption	decryption	IV	security
ECB	$C_i = E_K(P_i)$	$P_i = D_K(C_i)$	none	–
CBC	$C_i = E_K(P_i \oplus C_{i-1})$	$P_i = D_K(C_i) \oplus C_{i-1}$	unique	+(+)
CFB	$C_i = P_i \oplus E_K(C_{i-1})$	$P_i = C_i \oplus E_K(C_{i-1})$	unique!	+
OFB	$C_i = P_i \oplus S_i, S_i = E_K(S_{i-1})$	$P_i = C_i \oplus S_i$	unique	+

As stated above a block-cipher is needed to make the stream-ciphers work. The following block-ciphers are part of LEDA:

block-cipher	block size / bits	key-size / bits
Blowfish	64	32 – 448
Twofish	128	128 – 256
Rijndael (AES)	128	128 – 256

Comparing the ciphers in terms of performance *Blowfish* comes out worst (probably because of the smaller block size). Our implementation of *Twofish* is slightly faster than that of *Rijndael*. In terms of security it is hard to rank the three ciphers. All of them have been intensively cryptanalyzed and no weaknesses have been found so far. *Blowfish* is used in the *ssh* command of Unix, *Rijndael* won the contest for the Advanced Encryption Standard (AES), and *Twofish* reached the final round of that contest.

11.4 Example for a Stream-Cipher (CBCCoder)

1. Definition

A stream-cipher is a coder that encrypts and decrypts data streams. In this section we discuss the interface of such a coder by an example: *CBCCoder*< *BlkCipher* >. Every stream-cipher in LEDA uses a block-cipher *BlkCipher* which is specified as a template parameter. (More information about stream-ciphers and block-ciphers can be found in Section 11.3.) The following stream-ciphers are available: *ECBCoder*, *CBCCoder*, *CFBCoder* and *OFBCoder*. All of them, except for *OFBCoder*, support fast seek operations (see Section 10.22). The available block-ciphers are: *Blowfish*, *Twofish* and *Rijndael*.

```
#include < LEDA/coding/stream_ciphers.h >
```

2. Creation

```
CBCCoder< BlkCipher > C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
                        bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
CBCCoder< BlkCipher > C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C.calculate_length_of_encoded_data(uint32 input_length)</i>	calculates the length (in bytes) of the output when encoding some input of the given length with the current settings. (This function is helpful for encoding memory chunks (see below).)

- uint32* *C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 encodes the memory chunk starting at *in_buf* with size *in_len* into the buffer starting at *out_buf* with size *out_len*. The function returns actual length of the encoded chunk which may be smaller than *out_len*. If the output buffer is too small for the encoded data the failure flag will be set (see below). **Note:** The output data is slightly longer than the input data due to padding and header data.
- uint32* *C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)*
 decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
- streambuf** *C.get_src_stream()* returns the current source stream.
- void* *C.set_src_stream(streambuf * src_stream, bool own_stream = false)*
 sets the source stream (cf. constructor).
- void* *C.set_src_file(const char * file_name)*
 sets a file as source stream.
- streambuf** *C.get_tgt_stream()* returns the current target stream.
- void* *C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)*
 sets the target stream (cf. constructor).
- void* *C.set_tgt_file(const char * file_name)*
 sets a file as target stream.
- void* *C.reset(bool keep_key = true)*
 puts *C* in the same state as the default constructor. If *keep_key* is false the key is set to the empty key. In any case the initialization vector is set to *nil*.
- bool* *C.failed()* returns *true* if an error occurred.
- bool* *C.finished()* returns *true* if the coding is finished.
- string* *C.get_description()* provides a description for *C*.

Additional Operations

- uint16* *C.get_default_key_size()*
 returns the default key size.

<i>uint16</i>	<i>C.get_accepted_key_size(uint16& min, uint16& max)</i>	provides the minimum and maximum key size (in bytes). The return value is the default key size.
<i>void</i>	<i>C.set_key(const CryptKey& key)</i>	sets the key.
<i>bool</i>	<i>C.has_key()</i>	queries whether a key has been set.
<i>CryptKey</i>	<i>C.get_key()</i>	returns the current key.
<i>BlkCipher*</i>	<i>C.get_block_cipher()</i>	returns the underlying block-cipher.
<i>void</i>	<i>C.set_initialization_vector(const byte * iv)</i>	sets a user defined initialization vector (IV). The size of <i>iv</i> must be at least the block size of <i>BlkCipher</i> . (If no IV is provided by the user then <i>C</i> generates its own.)
<i>const byte*</i>	<i>C.get_initialization_vector()</i>	returns the user defined IV. (If no IV has been specified then <i>nil</i> is returned.)

11.5 Authentication (OMACCoder)

1. Definition

The class *OMACCoder* can be used for authentication. It implements the One-Key CBC MAC algorithm by Iwata and Kurosawa [49]. A MAC (= message authentication code) is a kind of checksum that is generated for a message *m*. In contrast to a usual checksum a MAC does not only depend on *m* but also on a secret key *k*. A MAC can be used if a sender wants to transfer *m* through an insecure channel to a receiver. If the sender also transmits the MAC then the receiver can verify that *m* has not been altered and that it originates from someone who knows *k*.

Important: *OMACCoder* does not encipher or decipher any data, it only computes and verifies MACs!

The behaviour of this coder depends on the *MAC_in_stream* flag. If it is false then encoding and decoding are equivalent: Both methods copy the source stream to the target stream and compute a MAC. If the flag is true then in encoding mode the source stream is copied to the target stream, a MAC is computed and appended to the target stream. In decoding mode the MAC at the end of source stream is removed and the original data is copied to the target stream, a MAC is computed and compared with the MAC found in the source stream. If the two MACs differ an error is signaled. The method *MAC_is_valid* may be used to check whether the source stream is authentic.

The class *OMACCoder*< *BlkCipher* > is parameterized with a block-cipher *BlkCipher*, which can be one of the following: *Rijndael* (default), *Blowfish*, *Twofish* (see Section 11.3 for more information). *OMACCoder* also supports fast seek operations (see Section 10.22).

```
#include < LEDA/coding/authentication.h >
```

2. Creation

```
OMACCoder< BlkCipher > C(streambuf * src_stream = 0,
                          streambuf * tgt_stream = 0, bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
OMACCoder< BlkCipher > C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

<i>void</i>	<i>C.encode()</i>	encodes the source stream and writes the output to the target stream.
<i>void</i>	<i>C.decode()</i>	decodes the source stream and writes the output to the target stream.
<i>uint32</i>	<i>C.calculate_length_of_encoded_data(uint32 input_length)</i>	calculates the length (in bytes) of the output when encoding some input of the given length with the current settings. (This function is helpful for encoding memory chunks (see below).)
<i>uint32</i>	<i>C.encode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	encodes the memory chunk starting at <i>in_buf</i> with size <i>in_len</i> into the buffer starting at <i>out_buf</i> with size <i>out_len</i> . The function returns actual length of the encoded chunk which may be smaller than <i>out_len</i> . If the output buffer is too small for the encoded data the failure flag will be set (see below). Note: The output data is slightly longer than the input data due to padding and header data.
<i>uint32</i>	<i>C.decode_memory_chunk(const char * in_buf, uint32 in_len, char * out_buf, uint32 out_len)</i>	decodes a memory chunk. The meaning of the parameters and the return value is the same as in the previous function.
<i>streambuf*</i>	<i>C.get_src_stream()</i>	returns the current source stream.
<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.

<i>void</i>	<i>C.reset(bool keep_parameters = true)</i>	puts <i>C</i> in the same state as the default constructor. If <i>keep_parameters</i> is false the parameters are set to their default values and the key is set to the empty key.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if the coding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> .

Additional Operations

<i>uint16</i>	<i>C.get_default_key_size()</i>	returns the default key size.
<i>uint16</i>	<i>C.get_accepted_key_size(uint16& min, uint16& max)</i>	provides the minimum and maximum key size (in bytes). The return value is the default key size.
<i>void</i>	<i>C.set_key(const CryptKey& key)</i>	sets the key.
<i>bool</i>	<i>C.has_key()</i>	queries whether a key has been set.
<i>CryptKey</i>	<i>C.get_key()</i>	returns the current key.
<i>const byte*</i>	<i>C.check()</i>	checks the source stream and returns the computed MAC. No target stream needs to be set. (If a target stream is set check coincides with decode).
<i>bool</i>	<i>C.MAC_is_valid()</i>	returns whether <i>C</i> has a valid MAC.
<i>string</i>	<i>C.get_MAC_as_hex_string()</i>	returns the MAC for the stream that has been processed last as hexadecimal string.
<i>const byte*</i>	<i>C.compute_MAC(string str)</i>	computes a MAC for a string. (Sets source and target stream to <i>nil</i> .)
<i>void</i>	<i>C.set_MAC_in_stream_flag(bool mac_in_stream)</i>	sets the <i>MAC_in_stream</i> flag.
<i>bool</i>	<i>C.get_MAC_in_stream_flag()</i>	returns the <i>MAC_in_stream</i> flag.

11.6 Automatic Decoder supporting Cryptography (CryptAutoDecoder)

1. Definition

The class *CryptAutoDecoder* is an extension of *AutoDecoder*. It can be used for decoding encrypted streams (in particular if the coder used for encoding is unknown). In order to decrypt a stream a key must be provided by the user because the key is – of course – not stored in the encrypted stream. There are three possibilities to specify a key: as a *CryptKey*, as a key stream or as a key file. Sometimes it may be necessary to provide several keys to *CryptAutoDecoder*. E.g., if you use *CoderPipe2< OMACCoder<>, OFBCoder<> >* to encode a stream two keys are needed for decoding. Therefore, *CryptAutoDecoder* maintains a list of keys for decoding.

```
#include < LEDA/coding/crypt_auto_decoder.h >
```

2. Creation

```
CryptAutoDecoder C(streambuf * src_stream = 0, streambuf * tgt_stream = 0,
    bool own_streams = false);
```

creates an instance *C* which uses the given source and target streams. If *own_streams* is set, then *C* is responsible for the destruction of the streams, otherwise the pointers *src_stream* and *tgt_stream* must be valid during the life-time of *C*.

```
CryptAutoDecoder C(const char * src_file_name, const char * tgt_file_name);
```

creates an instance *C* which uses file-streams for input and output.

3. Operations

Standard Operations

```
void C.decode() decodes the source stream and writes the output to the target stream.
```

```
uint32 C.decode_memory_chunk(const char * in_buf, uint32 in_len,
    char * out_buf, uint32 out_len)
    decodes the memory chunk starting at in_buf with size in_len into the buffer starting at out_buf with size out_len. The function returns actual length of the encoded chunk which may be smaller than out_len. If the output buffer is too small for the decoded data the failure flag will be set (see below).
```

```
streambuf* C.get_src_stream() returns the current source stream.
```

<i>void</i>	<i>C.set_src_stream(streambuf * src_stream, bool own_stream = false)</i>	sets the source stream (cf. constructor).
<i>void</i>	<i>C.set_src_file(const char * file_name)</i>	sets a file as source stream.
<i>streambuf*</i>	<i>C.get_tgt_stream()</i>	returns the current target stream.
<i>void</i>	<i>C.set_tgt_stream(streambuf * tgt_stream, bool own_Stream = false)</i>	sets the target stream (cf. constructor).
<i>void</i>	<i>C.set_tgt_file(const char * file_name)</i>	sets a file as target stream.
<i>void</i>	<i>C.reset()</i>	puts <i>C</i> in exactly the same state as the default constructor.
<i>bool</i>	<i>C.failed()</i>	returns <i>true</i> if an error occurred.
<i>bool</i>	<i>C.finished()</i>	returns <i>true</i> if decoding is finished.
<i>string</i>	<i>C.get_description()</i>	provides a description for <i>C</i> . After decoding this includes a description of the coder that has been used for encoding the stream.

Additional Operations

<i>coder_base*</i>	<i>C.get_coder()</i>	after decoding this function returns the coder that has actually been used to decode the stream.
<i>bool</i>	<i>C.has_key()</i>	returns whether the key list is not empty.
<i>list<CryptKey></i>	<i>C.get_keys()</i>	returns the current list of keys.
<i>void</i>	<i>C.set_key(const CryptKey& key)</i>	sets the key that should be used for decoding.
<i>void</i>	<i>C.add_key(const CryptKey& key)</i>	adds a key to the key list.
<i>void</i>	<i>C.set_keys_in_stream(streambuf * key_stream)</i>	makes the key list equal to the key(s) in <i>key_stream</i> .
<i>void</i>	<i>C.add_keys_in_stream(streambuf * key_stream)</i>	adds the key(s) in <i>key_stream</i> to the key list.
<i>void</i>	<i>C.set_keys_in_file(const char * file_name)</i>	makes the key list equal to the key(s) in the given file.

11.7 Secure Socket Streambuffer (*secure_socket_streambuf*)

1. Definition

An instance *sb* of class *secure_socket_streambuf* can be used as an adapter: It turns a *leda_socket* *s* into a C++-streambuf object. This object can be used in standard C++ *ostreams* and *istreams*, which makes the communication through the socket easier. Moreover, *secure_socket_streambuf* uses cryptography to secure the communication. Every piece of data is authenticated, (possibly) compressed and encrypted before it is sent.

If two parties want to use the class *secure_socket_streambuf* to exchange data they have to do the following. First they establish a connection through *leda_sockets*. Then each party constructs an instance of the class *secure_socket_streambuf* which is attached to its socket. (An example showing how to this can be found at the end of Section 4.14; simply replace “*socket_streambuf*” by “*secure_socket_streambuf*” and add the passphrase(s).)

The communication between two instances of the class *secure_socket_streambuf* can be divided in two phases. In the first phase the two parties negotiate session parameters like packet sizes and they also agree on a so-called session-seed which will be explained later. In the second phase the actual user data is exchanged. Each phases is protected with cryptography. The authentication and encryption keys for the first phase are generated in a deterministic way from the user-supplied passphrase(s). They are called master keys because they remain the same as long as the passphrases are not changed. In order to protect the master keys we use them only during the first phase, which consists of two messages from each party. After that we use the random session seed (in addition to the passphrases) to compute session keys which are used during the second phase.

```
#include < LEDA/coding/secure_socket_streambuf.h >
```

2. Creation

```
secure_socket_streambuf sb(leda_socket& s, const CryptByteString& auth_passphrase,
    const CryptByteString& cipher_passphrase,
    uint32 out_buf_sz = DefaultBufferSize,
    uint32 in_buf_sz = DefaultBufferSize,
    bool enable_compression = false,
    bool send_acknowledge = false);
```

creates a *sb* and attaches it to the socket *s*. The two passphrases are used to generate the keys for authentication and encryption. The parameters *out_buf_sz* and *in_buf_sz* determine the maximum size of the out-buffer and the in-buffer. The parameter *enable_compression* determines whether compression is used. *send_acknowledge* specifies whether an acknowledgement is sent for every received packet. *Precondition*: The connection between the server and the client must have been established when *sb* is created.

```
secure_socket_streambuf sb(leda_socket& s, const CryptByteString& passphrase,
    uint32 out_buf_sz = DefaultBufferSize,
    uint32 in_buf_sz = DefaultBufferSize,
    bool enable_compression = false,
    bool send_acknowledge = false);
```

as above, but the same *passphrase* is used for generating both the authentication and the encryption key. However, it is still guaranteed that two different keys are used.

3. Operations

The class *secure_socket_streambuf* inherits most of its operations from the class *streambuf* that belongs to the C++ standard library. Usually there is no need to call these operations explicitly. (You can find documentation for *streambuf* at <http://www.cplusplus.com>)

<i>bool</i>	<i>sb.failed()</i>	returns whether a failure has occurred.
<i>string</i>	<i>sb.get_error()</i>	returns an error message (if available).
<i>void</i>	<i>sb.sputEOF()</i>	signals the end of the transmission to the receiving socket, so that it does not wait for further data. (This function is called automatically in the destructor unless it has been called explicitly by the user. If <i>sb</i> is not immediately destroyed after the end of the transmission then you should call <i>sputEOF</i> explicitly, otherwise the receiving party might incur a timeout error.)
<i>bool</i>	<i>sb.has_put_EOF()</i>	returns whether EOF has already been sent.
<i>bool</i>	<i>sb.has_got_EOF()</i>	returns whether EOF has already been received.
<i>leda_socket</i> &	<i>sb.get_socket()</i>	returns the socket to which <i>sb</i> is attached.
<i>uint32</i>	<i>sb.get_outgoing_packet_size()</i>	returns the (actual) outgoing packet size.
<i>uint32</i>	<i>sb.get_incoming_packet_size()</i>	returns the (actual) incoming packet size.
<i>bool</i>	<i>sb.uses_compression()</i>	returns whether <i>sb</i> compresses outgoing packets before sending.
<i>bool</i>	<i>sb.waits_for_acknowledge()</i>	returns whether <i>sb</i> expects an acknowledgement for outgoing packets.

bool *sb*.sends_acknowledge()

returns whether *sb* sends an acknowledgement for incoming packets.

Chapter 12

Graphs and Related Data Types

12.1 Graphs (graph)

1. Definition

An instance G of the data type *graph* consists of a list V of nodes and a list E of edges (*node* and *edge* are item types). Distinct graph have disjoint node and edge lists. The value of a variable of type *node* is either the node of some graph, or the special value *nil* (which is distinct from all nodes), or is undefined (before the first assignment to the variable). A corresponding statement is true for the variables of type *edge*.

A graph with empty node list is called *empty*. A pair of nodes $(v, w) \in V \times V$ is associated with every edge $e \in E$; v is called the *source* of e and w is called the *target* of e , and v and w are called *endpoints* of e . The edge e is said to be *incident* to its endpoints.

A graph is either *directed* or *undirected*. The difference between directed and undirected graph is the way the edges incident to a node are stored and how the concept *adjacent* is defined.

In directed graph two lists of edges are associated with every node v : $adj_edges(v) = \{e \in E \mid v = source(e)\}$, i.e., the list of edges starting in v , and $in_edges(v) = \{e \in E \mid v = target(e)\}$, i.e., the list of edges ending in v . The list $adj_edges(v)$ is called the adjacency list of node v and the edges in $adj_edges(v)$ are called the edges *adjacent* to node v . For directed graph we often use $out_edges(v)$ as a synonym for $adj_edges(v)$.

In undirected graph only the list $adj_edges(v)$ is defined for every every node v . Here it contains all edges incident to v , i.e., $adj_edges(v) = \{e \in E \mid v \in \{source(e), target(e)\}\}$. An undirected graph may not contain self-loops, i.e., it may not contain an edge whose source is equal to its target.

In a directed graph an edge is adjacent to its source and in an undirected graph it is adjacent to its source and target. In a directed graph a node w is adjacent to a node v if

there is an edge $(v, w) \in E$; in an undirected graph w is adjacent to v if there is an edge (v, w) or (w, v) in the graph.

A directed graph can be made undirected and vice versa: $G.\text{make_undirected}()$ makes the directed graph G undirected by appending for each node v the list $\text{in_edges}(v)$ to the list $\text{adj_edges}(v)$ (removing self-loops). Conversely, $G.\text{make_directed}()$ makes the undirected graph G directed by splitting for each node v the list $\text{adj_edges}(v)$ into the lists $\text{out_edges}(v)$ and $\text{in_edges}(v)$. Note that these two operations are not exactly inverse to each other. The data type *ugraph* (cf. section 12.4) can only represent undirected graph.

Reversal Information, Maps and Faces

The reversal information of an edge e is accessed through $G.\text{reversal}(e)$, it has type *edge* and may or may not be defined ($= \text{nil}$). Assume that $G.\text{reversal}(e)$ is defined and let $e' = G.\text{reversal}(e)$. Then $e = (v, w)$ and $e' = (w, v)$ for some nodes v and w , $G.\text{reversal}(e')$ is defined and $e = G.\text{reversal}(e')$. In addition, $e \neq e'$. In other words, *reversal* deserves its name.

We call a directed graph *bidirected* if the reversal information can be properly defined for all edges in G , resp. if there exists a bijective function $\text{rev} : E \rightarrow E$ with the properties of *reversal* as described above and we call a bidirected graph a *map* if all edges have their reversal information defined. Maps are the data structure of choice for embedded graph. For an edge e of a map G let $\text{face_cycle_succ}(e) = \text{cyclic_adj_pred}(\text{reversal}(e))$ and consider the sequence $e, \text{face_cycle_succ}(e), \text{face_cycle_succ}(\text{face_cycle_succ}(e)), \dots$. The first edge to repeat in this sequence is e (why?) and the set of edges appearing in this sequence is called the *face cycle* containing e . Each edge is contained in some face cycle and face cycles are pairwise disjoint. Let f be the number of face cycles, n be the number of (non-isolated) nodes, m be the number of edges, and let c be the number of (non-singleton) connected components. Then $g = (m/2 - n - f)/2 + c$ is called the *genus* of the map [89] (note that $m/2$ is the number of edges in the underlying undirected graph). The genus is zero if and only if the map is planar, i.e., there is an embedding of G into the plane such that for every node v the counter-clockwise ordering of the edges around v agrees with the cyclic ordering of v 's adjacency list. (In order to check whether a map is planar, you may use the function $\text{Is_Plane_Map}()$ in 12.23.)

If a graph G is a map the faces of G can be constructed explicitly by $G.\text{compute_faces}()$. Afterwards, the faces of G can be traversed by different iterators, e.g., $\text{for_all_faces}(f, G)$ iterates over all faces, $\text{for_all_adj_faces}(v)$ iterates over all faces adjacent to node v . By using face maps or arrays (data types *face_map* and *face_array*) additional information can be associated with the faces of a graph. Note that any update operation performed on G invalidates the list of faces. See the section on face operations for a complete list of available operations for faces.

```
#include < LEDA/graph/graph.h >
```

2. Creation

graph G ; creates an object G of type *graph* and initializes it to the empty directed graph.

graph $G(\text{int } n_slots, \text{int } e_slots)$;

this constructor specifies the numbers of free data slots in the nodes and edges of G that can be used for storing the entries of node and edge arrays. See also the description of the *use_node_data*() and *use_edge_data*() operations in 12.8 and 12.9.

3. Operations

void $G.\text{init}(\text{int } n, \text{int } m)$ this operation has to be called for semi-dynamic graph (if compiled with $-DGRAPH_REP = 2$) immediately after the constructor to specify upper bounds n and m for the number of nodes and edges respectively. This operation has no effect if called for the (fully-dynamic) standard graph representation.

a) Access operations

int $G.\text{outdeg}(\text{node } v)$ returns the number of edges adjacent to node v ($|\text{adj_edges}(v)|$).

int $G.\text{indeg}(\text{node } v)$ returns the number of edges ending at v ($|\text{in_edges}(v)|$) if G is directed and zero if G is undirected).

int $G.\text{degree}(\text{node } v)$ returns $\text{outdeg}(v) + \text{indeg}(v)$.

node $G.\text{source}(\text{edge } e)$ returns the source node of edge e .

node $G.\text{target}(\text{edge } e)$ returns the target node of edge e .

node $G.\text{opposite}(\text{node } v, \text{edge } e)$ returns $\text{target}(e)$ if $v = \text{source}(e)$ and $\text{source}(e)$ otherwise.

node $G.\text{opposite}(\text{edge } e, \text{node } v)$ same as above.

int $G.\text{number_ofNodes}()$ returns the number of nodes in G .

int $G.\text{number_ofEdges}()$ returns the number of edges in G .

const list<node>& $G.\text{allNodes}()$ returns the list V of all nodes of G .

const list<edge>& $G.\text{allEdges}()$ returns the list E of all edges of G .

<i>list<edge></i>	<i>G.adj_edges(node v)</i>	returns <i>adj_edges(v)</i> .
<i>list<edge></i>	<i>G.out_edges(node v)</i>	returns <i>adj_edges(v)</i> if <i>G</i> is directed and the empty list otherwise.
<i>list<edge></i>	<i>G.in_edges(node v)</i>	returns <i>in_edges(v)</i> if <i>G</i> is directed and the empty list otherwise.
<i>list<node></i>	<i>G.adj_nodes(node v)</i>	returns the list of all nodes adjacent to <i>v</i> .
<i>node</i>	<i>G.first_node()</i>	returns the first node in <i>V</i> .
<i>node</i>	<i>G.last_node()</i>	returns the last node in <i>V</i> .
<i>node</i>	<i>G.choose_node()</i>	returns a random node of <i>G</i> (nil if <i>G</i> is empty).
<i>node</i>	<i>G.succ_node(node v)</i>	returns the successor of node <i>v</i> in <i>V</i> (nil if it does not exist).
<i>node</i>	<i>G.pred_node(node v)</i>	returns the predecessor of node <i>v</i> in <i>V</i> (nil if it does not exist).
<i>edge</i>	<i>G.first_edge()</i>	returns the first edge in <i>E</i> .
<i>edge</i>	<i>G.last_edge()</i>	returns the last edge in <i>E</i> .
<i>edge</i>	<i>G.choose_edge()</i>	returns a random edge of <i>G</i> (nil if <i>G</i> is empty).
<i>edge</i>	<i>G.succ_edge(edge e)</i>	returns the successor of edge <i>e</i> in <i>E</i> (nil if it does not exist).
<i>edge</i>	<i>G.predEdge(edge e)</i>	returns the predecessor of edge <i>e</i> in <i>E</i> (nil if it does not exist).
<i>edge</i>	<i>G.first_adjEdge(node v)</i>	returns the first edge in the adjacency list of <i>v</i> (nil if this list is empty).
<i>edge</i>	<i>G.last_adjEdge(node v)</i>	returns the last edge in the adjacency list of <i>v</i> (nil if this list is empty).
<i>edge</i>	<i>G.adj_succ(edge e)</i>	returns the successor of edge <i>e</i> in the adjacency list of node <i>source(e)</i> (nil if it does not exist).
<i>edge</i>	<i>G.adj_pred(edge e)</i>	returns the predecessor of edge <i>e</i> in the adjacency list of node <i>source(e)</i> (nil if it does not exist).
<i>edge</i>	<i>G.cyclic_adj_succ(edge e)</i>	returns the cyclic successor of edge <i>e</i> in the adjacency list of node <i>source(e)</i> .
<i>edge</i>	<i>G.cyclic_adj_pred(edge e)</i>	returns the cyclic predecessor of edge <i>e</i> in the adjacency list of node <i>source(e)</i> .

<i>edge</i>	$G.first_in_edge(node\ v)$	returns the first edge of $in_edges(v)$ (nil if this list is empty).
<i>edge</i>	$G.last_in_edge(node\ v)$	returns the last edge of $in_edges(v)$ (nil if this list is empty).
<i>edge</i>	$G.in_succ(edge\ e)$	returns the successor of edge e in $in_edges(target(e))$ (nil if it does not exist).
<i>edge</i>	$G.in_pred(edge\ e)$	returns the predecessor of edge e in $in_edges(target(e))$ (nil if it does not exist).
<i>edge</i>	$G.cyclic_in_succ(edge\ e)$	returns the cyclic successor of edge e in $in_edges(target(e))$ (nil if it does not exist).
<i>edge</i>	$G.cyclic_in_pred(edge\ e)$	returns the cyclic predecessor of edge e in $in_edges(target(e))$ (nil if it does not exist).
<i>bool</i>	$G.is_directed()$	returns true iff G is directed.
<i>bool</i>	$G.is_undirected()$	returns true iff G is undirected.
<i>bool</i>	$G.empty()$	returns true iff G is empty.

b) Update operations

<i>node</i>	$G.new_node()$	adds a new node to G and returns it.
<i>node</i>	$G.new_node(node\ u, int\ dir)$	adds a new node v to G and returns it. v is inserted in front of ($dir = leda::before$) or behind ($dir = leda::behind$) node u into the list of all nodes.
<i>edge</i>	$G.new_edge(node\ v, node\ w)$	adds a new edge (v, w) to G by appending it to $adj_edges(v)$ and to $in_edges(w)$ (if G is directed) or $adj_edges(w)$ (if G is undirected), and returns it.
<i>edge</i>	$G.new_edge(edge\ e, node\ w, int\ dir = leda::behind)$	adds a new edge $x = (source(e), w)$ to G . x is inserted in front of ($dir = leda::before$) or behind ($dir = leda::behind$) edge e into $adj_edges(source(e))$ and appended to $in_edges(w)$ (if G is directed) or $adj_edges(w)$ (if G is undirected). Here $leda::before$ and $leda::behind$ are pre-defined constants. The operation returns the new edge x . <i>Precondition:</i> $source(e) \neq w$ if G is undirected.

<i>edge</i>	<i>G.new_edge</i> (<i>node v</i> , <i>edge e</i> , <i>int dir = leda::behind</i>)	adds a new edge $x = (v, target(e))$ to G . x is appended to $adj_edges(v)$ and inserted in front of ($dir = leda::before$) or behind ($dir = leda::behind$) edge e into $in_edges(target(e))$ (if G is directed) or $adj_edges(target(e))$ (if G is undirected). The operation returns the new edge x . <i>Precondition:</i> $target(e) \neq v$ if G is undirected.
<i>edge</i>	<i>G.new_edge</i> (<i>edge e1</i> , <i>edge e2</i> , <i>int d1 = leda::behind</i> , <i>int d2 = leda::behind</i>)	adds a new edge $x = (source(e1), target(e2))$ to G . x is inserted in front of (if $d1 = leda::before$) or behind (if $d1 = leda::behind$) edge $e1$ into $adj_edges(source(e1))$ and in front of (if $d2 = leda::before$) or behind (if $d2 = leda::behind$) edge $e2$ into $in_edges(target(e2))$ (if G is directed) or $adj_edges(target(e2))$ (if G is undirected). The operation returns the new edge x .
<i>node</i>	<i>G.merge_nodes</i> (<i>node v1</i> , <i>node v2</i>)	experimental.
<i>node</i>	<i>G.merge_nodes</i> (<i>edge e1</i> , <i>node v2</i>)	experimental.
<i>node</i>	<i>G.split_edge</i> (<i>edge e</i> , <i>edge& e1</i> , <i>edge& e2</i>)	experimental
<i>void</i>	<i>G.hide_edge</i> (<i>edge e</i>)	removes edge e temporarily from G until restored by $G.restore_edge(e)$.
<i>void</i>	<i>G.hide_edges</i> (<i>const list<edge>& el</i>)	hides all edges in el .
<i>bool</i>	<i>G.is_hidden</i> (<i>edge e</i>)	returns <i>true</i> if e is hidden and <i>false</i> otherwise.
<i>list<edge></i>	<i>G.hidden_edges</i> ()	returns the list of all hidden edges of G .
<i>void</i>	<i>G.restore_edge</i> (<i>edge e</i>)	restores e by appending it to $adj_edges(source(e))$ and to $in_edges(target(e))$ ($adj_edges(target(e))$ if G is undirected). <i>Precondition:</i> e is hidden and neither $source(e)$ nor $target(e)$ is hidden.
<i>void</i>	<i>G.restore_edges</i> (<i>const list<edge>& el</i>)	restores all edges in el .
<i>void</i>	<i>G.restore_allEdges</i> ()	restores all hidden edges.

<i>void</i>	<code>G.hide_node(node v)</code>	removes node v temporarily from G until restored by <code>G.restore_node(v)</code> . All non-hidden edges in <code>adj_edges(v)</code> and <code>in_edges(v)</code> are hidden too.
<i>void</i>	<code>G.hide_node(node v, list<edge>& h_edges)</code>	as above, in addition, the list of leaving or entering edges which are hidden as a result of hiding v are appended to <code>h_edges</code> .
<i>bool</i>	<code>G.is_hidden(node v)</code>	returns <i>true</i> if v is hidden and <i>false</i> otherwise.
<i>list<node></i>	<code>G.hidden_nodes()</code>	returns the list of all hidden nodes of G .
<i>void</i>	<code>G.restore_node(node v)</code>	restores v by appending it to the list of all nodes. Note that no edge adjacent to v that was hidden by <code>G.hide_node(v)</code> is restored by this operation.
<i>void</i>	<code>G.restore_all_nodes()</code>	restores all hidden nodes.
<i>void</i>	<code>G.del_node(node v)</code>	deletes v and all edges incident to v from G .
<i>void</i>	<code>G.delEdge(edge e)</code>	deletes the edge e from G .
<i>void</i>	<code>G.del_nodes(const list<node>& L)</code>	deletes all nodes in L from G .
<i>void</i>	<code>G.delEdges(const list<edge>& L)</code>	deletes all edges in L from G .
<i>void</i>	<code>G.delAllNodes()</code>	deletes all nodes from G .
<i>void</i>	<code>G.delAllEdges()</code>	deletes all edges from G .
<i>void</i>	<code>G.delAllFaces()</code>	deletes all faces from G .
<i>void</i>	<code>G.move_edge(edge e, node v, node w)</code>	moves edge e to source v and target w by appending it to <code>adj_edges(v)</code> and to <code>in_edges(w)</code> (if G is directed) or <code>adj_edges(w)</code> (if G is undirected).
<i>void</i>	<code>G.move_edge(edge e, edge e1, node w, int d = leda::behind)</code>	moves edge e to source <code>source(e1)</code> and target w by inserting it in front of (if $d = \text{leda::before}$) or behind (if $d = \text{leda::behind}$) edge $e1$ into <code>adj_edges(source(e1))</code> and by appending it to <code>in_edges(w)</code> (if G is directed) or <code>adj_edges(w)</code> (if G is undirected).

- void* `G.move_edge(edge e, node v, edge e2, int d = leda::behind)`
 moves edge e to source v and target $target(e2)$ by appending it to $adj_edges(v)$ and inserting it in front of (if $d = leda::before$) or behind (if $d = leda::behind$) edge $e2$ into $in_edges(target(e2))$ (if G is directed) or $adj_edges(target(e2))$ (if G is undirected).
- void* `G.move_edge(edge e, edge e1, edge e2, int d1 = leda::behind, int d2 = leda::behind)`
 moves edge e to source $source(e1)$ and target $target(e2)$ by inserting it in front of (if $d1 = leda::before$) or behind (if $d1 = leda::behind$) edge $e1$ into $adj_edges(source(e1))$ and in front of (if $d2 = leda::before$) or behind (if $d2 = leda::behind$) edge $e2$ into $in_edges(target(e2))$ (if G is directed) or $adj_edges(target(e2))$ (if G is undirected).
- edge* `G.rev_edge(edge e)` reverses e ($move_edge(e, target(e), source(e))$).
- void* `G.rev_allEdges()` reverses all edges of G .
- void* `G.sort_nodes(int (*cmp)(const node&, const node&))`
 the nodes of G are sorted according to the ordering defined by the comparing function cmp . Subsequent executions of `forall_nodes` step through the nodes in this order. (cf. TOPSORT1 in section 13).
- void* `G.sort_edges(int (*cmp)(const edge&, const edge&))`
 the edges of G and all adjacency lists are sorted according to the ordering defined by the comparing function cmp . Subsequent executions of `forall_edges` step through the edges in this order. (cf. TOPSORT1 in section 13).
- void* `G.sort_nodes(const node_array<T>& A)`
 the nodes of G are sorted according to the entries of `node_array A` (cf. section 12.8).
Precondition: T must be numerical, i.e., number type *int*, *float*, *double*, *integer*, *rational* or *real*.
- void* `G.sort_edges(const edge_array<T>& A)`
 the edges of G are sorted according to the entries of `edge_array A` (cf. section 12.9).
Precondition: T must be numerical, i.e., number type *int*, *float*, *double*, *integer*, *rational* or *real*.

- void* `G.bucket_sort_nodes(int l, int h, int (*ord)(const node&))`
 sorts the nodes of G using *bucket sort*
Precondition: $l \leq ord(v) \leq h$ for all nodes v .
- void* `G.bucket_sort_edges(int l, int h, int (*ord)(const edge&))`
 sorts the edges of G using *bucket sort*
Precondition: $l \leq ord(e) \leq h$ for all edges e .
- void* `G.bucket_sort_nodes(int (*ord)(const node&))`
 same as $G.bucket_sort_nodes(l, h, ord)$ with l (h) equal to the minimal (maximal) value of $ord(v)$.
- void* `G.bucket_sort_edges(int (*ord)(const edge&))`
 same as $G.bucket_sort_edges(l, h, ord)$ with l (h) equal to the minimal (maximal) value of $ord(e)$.
- void* `G.bucket_sort_nodes(const node_array<int>& A)`
 same as $G.bucket_sort_nodes(ord)$ with $ord(v) = A[v]$ for all nodes v of G .
- void* `G.bucket_sort_edges(const edge_array<int>& A)`
 same as $G.bucket_sort_edges(ord)$ with $ord(e) = A[e]$ for all edges e of G .
- void* `G.set_node_position(node v, node p)`
 moves node v in the list V of all nodes such that p becomes the predecessor of v . If $p = nil$ then v is moved to the front of V .
- void* `G.set_edge_position(edge e, edge p)`
 moves edge e in the list E of all edges such that p becomes the predecessor of e . If $p = nil$ then e is moved to the front of E .
- void* `G.permute_edges()` the edges of G and all adjacency lists are randomly permuted.
- list<edge>* `G.insert_reverse_edges()` for every edge (v, w) in G the reverse edge (w, v) is inserted into G . Returns the list of all inserted edges.
 Remark: the reversal information is not set by this function.
- void* `G.make_undirected()` makes G undirected by appending $in_edges(v)$ to $adj_edges(v)$ for all nodes v .
- void* `G.make_directed()` makes G directed by splitting $adj_edges(v)$ into $out_edges(v)$ and $in_edges(v)$.
- void* `G.clear()` makes G the empty graph.

<i>edge</i>	<code>G.new_map_edge(edge e1, edge e2)</code>	inserts a new edge $e = (source(e1), source(e2))$ after $e1$ into the adjacency list of $source(e1)$ and an edge r reversal to e after $e2$ into the adjacency list of $source(e2)$.
<i>list<edge></i>	<code>G.triangulate_map()</code>	triangulates the map G by inserting additional edges. The list of inserted edges is returned. <i>Precondition:</i> G must be connected. The algorithm ([47]) has running time $O(V + E)$.
<i>void</i>	<code>G.dual_map(graph& D)</code>	constructs the dual of G in D . The algorithm has linear running time. <i>Precondition:</i> G must be a map.

For backward compatibility

<i>edge</i>	<code>G.reverse(edge e)</code>	returns <i>reversal(e)</i> (historical).
<i>edge</i>	<code>G.succ_face_edge(edge e)</code>	returns <i>face_cycle_succ(e)</i> (historical).
<i>edge</i>	<code>G.next_face_edge(edge e)</code>	returns <i>face_cycle_succ(e)</i> (historical).
<i>edge</i>	<code>G.pred_face_edge(edge e)</code>	returns <i>face_cycle_pred(e)</i> (historical).

d) Faces and Planar Maps

<i>void</i>	<code>G.compute_faces()</code>	constructs the list of face cycles of G . <i>Precondition:</i> G is a map.
<i>face</i>	<code>G.face_of(edge e)</code>	returns the face of G to the left of edge e .
<i>face</i>	<code>G.adj_face(edge e)</code>	returns $G.face_of(e)$.
<i>void</i>	<code>G.print_face(face f)</code>	prints face f .
<i>int</i>	<code>G.number_of_faces()</code>	returns the number of faces of G .
<i>face</i>	<code>G.first_face()</code>	returns the first face of G . (nil if empty).
<i>face</i>	<code>G.last_face()</code>	returns the last face of G .
<i>face</i>	<code>G.choose_face()</code>	returns a random face of G (nil if G is empty).
<i>face</i>	<code>G.succ_face(face f)</code>	returns the successor of face f in the face list of G (nil if it does not exist).
<i>face</i>	<code>G.pred_face(face f)</code>	returns the predecessor of face f in the face list of G (nil if it does not exist).

<i>const list<face>&</i>	<i>G.all_faces()</i>	returns the list of all faces of G .
<i>list<face></i>	<i>G.adj_faces(node v)</i>	returns the list of all faces of G adjacent to node v in counter-clockwise order.
<i>list<node></i>	<i>G.adj_nodes(face f)</i>	returns the list of all nodes of G adjacent to face f in counter-clockwise order.
<i>list<edge></i>	<i>G.adj_edges(face)</i>	returns the list of all edges of G bounding face f in counter-clockwise order.
<i>int</i>	<i>G.size(face f)</i>	returns the number of edges bounding face f .
<i>edge</i>	<i>G.first_face_edge(face f)</i>	returns the first edge of face f in G .
<i>edge</i>	<i>G.split_face(edge e1, edge e2)</i>	<p>inserts the edge $e = (source(e_1), source(e_2))$ and its reversal into G and returns e.</p> <p><i>Precondition:</i> e_1 and e_2 are bounding the same face F.</p> <p>The operation splits F into two new faces.</p>
<i>face</i>	<i>G.join_faces(edge e)</i>	deletes edge e and its reversal r and updates the list of faces accordingly. The function returns a face that is affected by the operations (see the LEDA book for details).
<i>void</i>	<i>G.make_planar_map()</i>	<p>makes G a planar map by reordering the edges such that for every node v the ordering of the edges in the adjacency list of v corresponds to the counter-clockwise ordering of these edges around v for some planar embedding of G and constructs the list of faces.</p> <p><i>Precondition:</i> G is a planar bidirected graph (map).</p>
<i>list<edge></i>	<i>G.triangulate_planar_map()</i>	triangulates planar map G and recomputes its list of faces

e) Operations for undirected graphs

- edge* $G.new_edge(node\ v, edge\ e1, node\ w, edge\ e2, int\ d1 = leda::before, int\ d2 = leda::behind)$
 adds a new edge (v, w) to G by inserting it in front of (if $d1 = leda::before$) or behind (if $d1 = leda::behind$) edge $e1$ into $adj_edges(v)$ and in front of (if $d2 = leda::before$) or behind (if $d2 = leda::behind$) edge $e2$ into $adj_edges(w)$, and returns it.
Precondition: $e1$ is incident to v and $e2$ is incident to w and $v \neq w$.
- edge* $G.new_edge(node\ v, edge\ e, node\ w, int\ d = leda::behind)$
 adds a new edge (v, w) to G by inserting it in front of (if $d = leda::before$) or behind (if $d = leda::behind$) edge e into $adj_edges(v)$ and appending it to $adj_edges(w)$, and returns it.
Precondition: e is incident to v and $v \neq w$.
- edge* $G.new_edge(node\ v, node\ w, edge\ e, int\ d = leda::behind)$
 adds a new edge (v, w) to G by appending it to $adj_edges(v)$, and by inserting it in front of (if $d = leda::before$) or behind (if $d = leda::behind$) edge e into $adj_edges(w)$, and returns it.
Precondition: e is incident to w and $v \neq w$.
- edge* $G.adj_succ(edge\ e, node\ v)$
 returns the successor of edge e in the adjacency list of v .
Precondition: e is incident to v .
- edge* $G.adj_pred(edge\ e, node\ v)$
 returns the predecessor of edge e in the adjacency list of v .
Precondition: e is incident to v .
- edge* $G.cyclic_adj_succ(edge\ e, node\ v)$
 returns the cyclic successor of edge e in the adjacency list of v .
Precondition: e is incident to v .
- edge* $G.cyclic_adj_pred(edge\ e, node\ v)$
 returns the cyclic predecessor of edge e in the adjacency list of v .
Precondition: e is incident to v .

f) I/O Operations

<i>void</i>	<code>G.print_edge(edge e, ostream& O = cout)</code>	prints edge <i>e</i> on the output stream <i>O</i> . If <i>G</i> is directed <i>e</i> is represented by an arrow pointing from source to target. If <i>G</i> is undirected <i>e</i> is printed as an undirected line segment.
<i>void</i>	<code>G.print(string s, ostream& O = cout)</code>	prints <i>G</i> with header line <i>s</i> on the output stream <i>O</i> .
<i>void</i>	<code>G.print(ostream& O = cout)</code>	prints <i>G</i> on the output stream <i>O</i> .

g) Non-Member Functions

<i>node</i>	<code>source(edge e)</code>	returns the source node of edge <i>e</i> .
<i>node</i>	<code>target(edge e)</code>	returns the target node of edge <i>e</i> .
<i>graph*</i>	<code>graph_of(node v)</code>	returns a pointer to the graph that <i>v</i> belongs to.
<i>graph*</i>	<code>graph_of(edge e)</code>	returns a pointer to the graph that <i>e</i> belongs to.
<i>graph*</i>	<code>graph_of(face f)</code>	returns a pointer to the graph that <i>f</i> belongs to.
<i>face</i>	<code>face_of(edge e)</code>	returns the face of edge <i>e</i> .

h) Iteration

All iteration macros listed in this section traverse the corresponding node and edge lists of the graph, i.e. they visit nodes and edges in the order in which they are stored in these lists.

forall_nodes(*v*, *G*)
 { “the nodes of *G* are successively assigned to *v*” }

forall_edges(*e*, *G*)
 { “the edges of *G* are successively assigned to *e*” }

forall_rev_nodes(*v*, *G*)
 { “the nodes of *G* are successively assigned to *v* in reverse order” }

forall_rev_edges(*e*, *G*)
 { “the edges of *G* are successively assigned to *e* in reverse order” }

forall_hidden_edges(*e*, *G*)
 { “all hidden edges of *G* are successively assigned to *e*” }

forall_adj_edges(e, w)

{ “the edges adjacent to node w are successively assigned to e ” }

forall_out_edges(e, w)

a faster version of **forall_adj_edges** for directed graph.

forall_in_edges(e, w)

{ “the edges of $in_edges(w)$ are successively assigned to e ” }

forall_inout_edges(e, w)

{ “the edges of $out_edges(w)$ and $in_edges(w)$ are successively assigned to e ” }

forall_adj_undirected_edges(e, w)

like **forall_adj_edges** on the underlying undirected graph, no matter whether the graph is directed or undirected actually.

forall_adj_nodes(v, w)

{ “the nodes adjacent to node w are successively assigned to v ” }

Faces

Before using any of the following face iterators the list of faces has to be computed by calling $G.compute_faces()$. Note, that any update operation invalidates this list.

forall_faces(f, M)

{ “the faces of M are successively assigned to f ” }

forall_face_edges(e, f)

{ “the edges of face f are successively assigned to e ” }

forall_adj_faces(f, v)

{ “the faces adjacent to node v are successively assigned to f ” }

4. Implementation

Graphs are implemented by doubly linked lists of nodes and edges. Most operations take constant time, except for `all_nodes`, `all_edges`, `del_all_nodes`, `del_all_edges`, `make_map`, `make_planar_map`, `compute_faces`, `all_faces`, `make_bidirected`, `clear`, `write`, and `read` which take time $O(n + m)$, and `adj_edges`, `adj_nodes`, `out_edges`, `in_edges`, and `adj_faces` which take time $O(\text{output size})$ where n is the current number of nodes and m is the current number of edges. The space requirement is $O(n + m)$.

12.2 Parameterized Graphs (GRAPH)

1. Definition

A parameterized graph G is a graph whose nodes and edges contain additional (user defined) data. Every node contains an element of a data type $vtype$, called the node type of G and every edge contains an element of a data type $etype$ called the edge type of G . We use $\langle v, w, y \rangle$ to denote an edge (v, w) with information y and $\langle x \rangle$ to denote a node with information x .

All operations defined for the basic graph type $graph$ are also defined on instances of any parameterized graph type $GRAPH\langle vtype, etype \rangle$. For parameterized graph there are additional operations to access or update the information associated with its nodes and edges. Instances of a parameterized graph type can be used wherever an instance of the data type $graph$ can be used, e.g., in assignments and as arguments to functions with formal parameters of type $graph\&$. If a function $f(graph\& G)$ is called with an argument Q of type $GRAPH\langle vtype, etype \rangle$ then inside f only the basic graph structure of Q can be accessed. The node and edge entries are hidden. This allows the design of generic graph algorithms, i.e., algorithms accepting instances of any parametrized graph type as argument.

```
#include < LEDA/graph/graph.h >
```

2. Types

```
GRAPH<vtype, etype>:: node_value_type
```

the type of node data ($vtype$).

```
GRAPH<vtype, etype>:: edge_value_type
```

the type of edge data ($etype$).

3. Creation

$GRAPH\langle vtype, etype \rangle G$; creates an instance G of type $GRAPH\langle vtype, etype \rangle$ and initializes it to the empty graph.

4. Operations

```
const vtype& G.inf(node v)           returns the information of node v.
```

```
const vtype& G[node v]              returns a reference to G.inf(v).
```

```
const etype& G.inf(edge e)          returns the information of edge e.
```

```
const etype& G[edge e]              returns a reference to G.inf(e).
```

node_array<vtype>& G.node_data() makes the information associated with the nodes of G available as a node array of type *node_array<vtype>*.

edge_array<etype>& G.edge_data() makes the information associated with the edges of G available as an edge array of type *edge_array<etype>*.

void G.assign(node v, const vtype& x)
makes x the information of node v .

void G.assign(edge e, const etype& x)
makes x the information of edge e .

node G.new_node(const vtype& x)
adds a new node $\langle x \rangle$ to G and returns it.

node G.new_node(node u, const vtype& x, int dir)
adds a new node $v = \langle x \rangle$ to G and returns it. v is inserted in front of ($dir = \text{leda}::\text{before}$) or behind ($dir = \text{leda}::\text{behind}$) node u into the list of all nodes.

edge G.new_edge(node v, node w, const etype& x)
adds a new edge $\langle v, w, x \rangle$ to G by appending it to *adj_edges(v)* and to *in_edges(w)* and returns it.

edge G.new_edge(edge e, node w, const etype& x, int dir = leda::behind)
adds a new edge $\langle \text{source}(e), w, x \rangle$ to G by inserting it behind ($dir = \text{leda}::\text{behind}$) or in front of ($dir = \text{leda}::\text{before}$) edge e into *adj_edges(source(e))* and appending it to *in_edges(w)*. Returns the new edge.

edge G.new_edge(node v, edge e, const etype& x, int dir = leda::behind)
adds a new edge $\langle v, \text{target}(e), x \rangle$ to G by inserting it behind ($dir = \text{leda}::\text{behind}$) or in front of ($dir = \text{leda}::\text{before}$) edge e into *in_edges(target(e))* and appending it to *adj_edges(v)*. Returns the new edge.

edge G.new_edge(edge e1, edge e2, const etype& x, int d1 = leda::behind, int d2 = leda::behind)
adds a new edge $x = (\text{source}(e1), \text{target}(e2), x)$ to G . x is inserted in front of (if $d1 = \text{leda}::\text{before}$) or behind (if $d1 = \text{leda}::\text{behind}$) edge $e1$ into *adj_edges(source(e1))* and in front of (if $d2 = \text{leda}::\text{before}$) or behind (if $d2 = \text{leda}::\text{behind}$) edge $e2$ into *in_edges(target(e2))* (if G is directed) or *adj_edges(target(e2))* (if G is undirected). The operation returns the new edge x .

- edge* *G.new_edge*(*node v*, *edge e1*, *node w*, *edge e2*, *const etype& x*,
 int d1 = leda::behind, *int d2 = leda::behind*)
 adds a new edge (v, w, x) to G by inserting it in front of (if $d1 = leda::before$) or behind (if $d1 = leda::behind$) edge $e1$ into $adj_edges(v)$ and in front (if $d2 = leda::before$) or behind (if $d2 = leda::behind$) edge $e2$ into $adj_edges(w)$, and returns it.
 Precondition: G is undirected, $v \neq w$, $e1$ is incident to v , and $e2$ is incident to w .
- edge* *G.new_edge*(*node v*, *edge e*, *node w*, *const etype& x*, *int d = leda::behind*)
 adds a new edge (v, w, x) to G by inserting it in front of (if $d = leda::before$) or behind (if $d = leda::behind$) edge e into $adj_edges(v)$ and appending it to $adj_edges(w)$, and returns it.
 Precondition: G is undirected, $v \neq w$, $e1$ is incident to v , and e is incident to v .
- void* *G.sort_nodes*(*const list<node>& vl*)
 makes vl the node list of G .
 Precondition: vl contains exactly the nodes of G .
- void* *G.sort_edges*(*const list<edge>& el*)
 makes el the edge list of G .
 Precondition: el contains exactly the edges of G .
- void* *G.sort_nodes*()
 the nodes of G are sorted increasingly according to their contents.
 Precondition: $vtype$ is linearly ordered.
- void* *G.sort_edges*()
 the edges of G are sorted increasingly according to their contents.
 Precondition: $etype$ is linearly ordered.
- void* *G.write*(*string fname*)
 writes G to the file with name $fname$. The output operators $operator \ll (ostream\&, const vtype\&)$ and $operator \ll (ostream\&, const etype\&)$ (cf. section 1.6) must be defined.
- int* *G.read*(*string fname*)
 reads G from the file with name $fname$. The input operators $operator \gg (istream\&, vtype\&)$ and $operator \gg (istream\&, etype\&)$ (cf. section 1.6) must be defined. Returns error code
 1 if file $fname$ does not exist
 2 if graph is not of type $GRAPH<vtype, etype>$
 3 if file $fname$ does not contain a graph
 0 if reading was successful.

5. Implementation

Parameterized graph are derived from directed graph. All additional operations for manipulating the node and edge entries take constant time.

12.3 Static Graphs (*static_graph*)

1. Definition

1.1 Motivation. The data type *static_graph* representing static graph is the result of two observations:

First, most graph algorithms do not change the underlying graph, they work on a constant or static graph and second, different algorithms are based on different models (we call them *categories*) of graph.

The LEDA data type *graph* represents all types of graph used in the library, such as directed, undirected, and bidirected graph, networks, planar maps, and geometric graph. It provides the operations for all of these graph in one fat interface. For efficiency reasons it makes sense to provide special graph data types for special purposes. The template data type *static_graph*, which is parameterized with the graph category, provides specialized implementations for some of these graph types.

1.2 Static Graphs. A static graph consists of a fixed sequence of nodes and edges. The parameterized data type *static_graph*<*category*, *node_data*, *edge_data*> is used to represent static graph. The first template parameter *category* defines the graph category and is taken from {*directed_graph*, *bidirectional_graph*, *opposite_graph*} (see 1.3 for the details). The last two parameters are optional and can be used to define user-defined data structures to be included into the node and edge objects (see 1.4 for the details). An instance *G* of the parameterized data type *static_graph* contains a sequence *V* of nodes and a sequence *E* of edges. New nodes or edges can be appended only in a construction phase which has to be started by calling *G.start_construction*() and terminated by *G.finish_construction*(). For every node or edge *x* we define *index(x)* to be equal to the rank of *x* in its sequence. During the construction phase, the sequence of the source node index of all inserted edges must be non-decreasing. After the construction phase both sequences *V* and *E* are fixed.

1.3 Graph Categories. We distinguish between five categories where currently only the first three are supported by *static_graph*:

- Directed Graphs (*directed_graph*) represent the concept of a directed graph by providing the ability to iterate over all edges incident to a given node *v* and to ask for the target node of a given edge *e*.
- Bidirectional Graphs (*bidirectional_graph*) extend directed graph by supporting in addition iterations over all incoming edges at a given node *v* and to ask for the source node of a given edge *e*.

- Opposite Graphs (*opposite_graph*) are a variant of the bidirectional graph category. They do not support the computation of the source or target node of a given edge but allow walking from one terminal v of an edge e to the other *opposite one*.

Not yet implemented are bidirected and undirected graph.

1.4 Node and Edge Data. Static graph support several efficient ways - efficient compared to using *node_arrays*, *edge_arrays*, *node_maps*, and *edge_maps* - to associate data with the edges and nodes of the graph.

1.4.1 Dynamic Slot Assignment: It is possible to attach two optional template parameters *data_slots<int>* at compile time:

```
static_graph<directed_graph, data_slots<3>, data_slots<1> > G;
```

specifies a static directed graph G with three additional node slots and one additional edge slot. Node and edge arrays can use these data slots, instead of allocating an external array. This method is also supported for the standard LEDA data type *graph*. Please see the manual page for *node_array* resp. *edge_array* (esp. the operations *use_node_data* resp. *use_edge_data*) for the details.

The method is called *dynamic slot assignment* since the concrete arrays are assigned during runtime to the slots.

1.4.2 Static Slot Assignment: This method is even more efficient. A variant of the node and edge arrays, the so-called *node_slot* and *edge_slot* data types, are assigned to the slots during compilation time. These types take three parameters: the element type of the array, an integer slot number, and the type of the graph:

```
node_slot<E, graph_t, slot>;
edge_slot<E, graph_t, slot>;
```

Here is an example for the use of static slot assignment in a maxflow graph algorithm. It uses three node slots for storing distance, excess, and a successor node, and two edge slots for storing the flow and capacity.

```
typedef static_graph<opposite_graph, data_slots<3>, data_slots<2> > maxflow_graph;
node_slot<node, maxflow_graph, 0> succ;
node_slot<int, maxflow_graph, 1> dist;
node_slot<edge, maxflow_graph, 2> excess;
edge_slot<int, maxflow_graph, 0> flow;
edge_slot<int, maxflow_graph, 1> cap;
```

When using the data types *node_slot* resp. *edge_slot* one has to include the files *LEDA/graph/edge_slot.h*.

1.4.3 Customizable Node and Edge Types: It is also possible to pass any structure derived from *data_slots<int>* as second or third parameter. Thereby the nodes and edges are extended by *named* data members. These are added in addition to the data slots specified in the base type. In the example

```
struct flow_node:public data_slots<1>
{ int excess;
  int level;
}
```

```
struct flow_edge:public data_slots<2>
{ int flow;
  int cap;
}
```

```
typedef static_graph<bidirectional_graph, flow_node, flow_edge> flow_graph;
```

there are three data slots (one of them unnamed) associated with each node and four data slots (two of them unnamed) associated with each edge of a *flow_graph*.

The named slots can be used as follows:

```
flow_graph::node v;
forall_nodes(v, G) v->excess = 0;
```

```
#include < LEDA/graph/static_graph.h >
```

2. Creation

```
static_graph<category, node_data = data_slots < 0 >, edge_data = data_slots < 0 > > G;
```

creates an empty static graph *G*. *category* is either *directed_graph*, or *bidirectional_graph*, or *opposite_graph*. The use of the other parameters is explained in the section *Node and Edge Data* given above.

3. Types

static_graph::node the node type. **Note:** It is different from *graph::node*.

static_graph::edge the edge type. **Note:** It is different from *graph::edge*.

4. Operations

The interface consists of two parts. The first part - the basic interface - is independent from the actual graph category, the specified operations are common to all graph. The second part of the interface is different for every category and contains macros to iterate over incident edges or adjacent nodes and methods for traversing a given edge.

<i>void</i>	<code>G.start_construction(int n, int m)</code>	starts the construction phase for a graph with up to n nodes and m edges.
<i>node</i>	<code>G.new_node()</code>	creates a new node, appends it to V , and returns it. The operation may only be called during construction phase and at most n times.
<i>edge</i>	<code>G.new_edge(node v, node w)</code>	creates the edge (v, w) , appends it to E , and returns it. The operation may only be called during construction phase and at most m times. <i>Precondition:</i> All edges (u, v) of G with $index(u) < index(v)$ have been created before.
<i>void</i>	<code>G.finish_construction()</code>	terminates the construction phase.
<i>int</i>	<code>forall_nodes(v, G)</code>	v iterates over the node sequence.
<i>int</i>	<code>forall_edges(e, G)</code>	e iterates over the edge sequence.

Static Directed Graphs (`static_graph<directed_graph>`)

For this category the basic interface of `static_graph` is extended by the operations:

<i>node</i>	<code>G.target(edge e)</code>	returns the target node of e .
<i>node</i>	<code>G.outdeg(node v)</code>	returns the number of outgoing edges of v .
<i>int</i>	<code>forall_out_edges(e, v)</code>	e iterates over all edges with $source(e) = v$.

Static Bidirectional Graphs (`static_graph<bidirectional_graph>`)

For this category the basic interface of `static_graph` is extended by the operations:

<i>node</i>	<code>G.target(edge e)</code>	returns the target node of e .
<i>node</i>	<code>G.source(edge e)</code>	returns the source node of e .

<i>node</i>	$G.outdeg(node\ v)$	returns the number of outgoing edges of v .
<i>node</i>	$G.indeg(node\ v)$	returns the number of incoming edges of v .
<i>int</i>	$forallOutEdges(e, v)$	e iterates over all edges with $source(e) = v$.
<i>int</i>	$forallInEdges(e, v)$	e iterates over all edges with $target(e) = v$.

Static Opposite Graphs (*static_graph*<*opposite_graph*>)

For this category the basic interface of *static_graph* is extended by the operations:

<i>node</i>	$G.opposite(edge\ e, node\ v)$	returns the opposite to v along e .
<i>node</i>	$G.outdeg(node\ v)$	returns the number of outgoing edges of v .
<i>node</i>	$G.indeg(node\ v)$	returns the number of incoming edges of v .
<i>int</i>	$forallOutEdges(e, v)$	e iterates over all edges with $source(e) = v$.
<i>int</i>	$forallInEdges(e, v)$	e iterates over all edges with $target(e) = v$.

5. Example

The simple example illustrates how to create a small graph and assign some values. To see how static graph can be used in a max flow algorithm - please see the source file *mfs.c* in the directory *test/flow*.

```
#include <LEDA/graph/graph.h>
#include <LEDA/graph/node_slot.h>
#include <LEDA/graph/edge_slot.h>
#include <LEDA/core/array.h>

using namespace leda;

struct node_weight:public data_slots<0>
{ int weight; }

struct edge_cap:public data_slots<0>
{ int cap; }

typedef static_graph<opposite_graph, node_weight, edge_cap> static_graph;
typedef static_graph::node st_node;
typedef static_graph::edge st_edge;
```

```
int main ()
{
    static_graph G;
    array<st_node> v(4);
    array<st_edge> e(4);
    G.start_construction(4,4);

    for(int i =0; i < 4; i++) v[i] = G.new_node();

    e[0] = G.new_edge(v[0], v[1]);
    e[1] = G.new_edge(v[0], v[2]);
    e[2] = G.new_edge(v[1], v[2]);
    e[3] = G.new_edge(v[3], v[1]);
    G.finish_construction();
    st_node v;
    st_edge e;
    forall_nodes(v, G) v->weight = 1;
    forall_edges(e, G) e->cap = 10;

    return 0;
}
```

12.4 Undirected Graphs (`ugraph`)

1. Definition

An instance U of the data type *ugraph* is an undirected graph as defined in section 12.1.

```
#include < LEDA/graph/ugraph.h >
```

2. Creation

```
ugraph  $U$ ;          creates an instance  $U$  of type ugraph and initializes it to the empty
                    undirected graph.
```

```
ugraph  $U(const\ graph\&\ G)$ ;
                    creates an instance  $U$  of type ugraph and initializes it with an undi-
                    rected copy of  $G$ .
```

3. Operations

see section 12.1.

4. Implementation

see section 12.1.

12.5 Parameterized Ugraph (UGRAPH)

1. Definition

A parameterized undirected graph G is an undirected graph whose nodes and edges contain additional (user defined) data (cf. 12.2). Every node contains an element of a data type *vtype*, called the node type of G and every edge contains an element of a data type *etype* called the edge type of G .

```
#include < LEDA/graph/ugraph.h >
```

```
UGRAPH<vtype, etype>  $U$ ;
                    creates an instance  $U$  of type ugraph and initializes it to the empty
                    undirected graph.
```

2. Operations

see section 12.2.

3. Implementation

see section 12.2.

12.6 Planar Maps (`planar_map`)

1. Definition

An instance M of the data type `planar_map` is the combinatorial embedding of a planar graph, i.e., M is bidirected (for every edge (v, w) of M the reverse edge (w, v) is also in M) and there is a planar embedding of M such that for every node v the ordering of the edges in the adjacency list of v corresponds to the counter-clockwise ordering of these edges around v in the embedding.

```
#include <LEDA/graph/planar_map.h >
```

2. Creation

```
planar_map M(const graph& G);
```

creates an instance M of type `planar_map` and initializes it to the planar map represented by the directed graph G .

Precondition: G represents a bidirected planar map, i.e. for every edge (v, w) in G the reverse edge (w, v) is also in G and there is a planar embedding of G such that for every node v the ordering of the edges in the adjacency list of v corresponds to the counter-clockwise ordering of these edges around v in the embedding.

3. Operations

```
edge M.new_edge(edge e1, edge e2)
```

inserts the edge $e = (source(e_1), source(e_2))$ and its reversal into M and returns e .

Precondition: e_1 and e_2 are bounding the same face F .

The operation splits F into two new faces.

```
face M.deledge(edge e)
```

deletes the edge e and its reversal from M . The two faces adjacent to e are united to one new face which is returned.

```
edge M.split_edge(edge e)
```

splits edge $e = (v, w)$ and its reversal $r = (w, v)$ into edges (v, u) , (u, w) , (w, u) , and (u, v) . Returns the edge (u, w) .

```
node M.new_node(const list<edge>& el)
```

splits the face bounded by the edges in el by inserting a new node u and connecting it to all source nodes of edges in el .

Precondition: all edges in el bound the same face.

```
node M.new_node(face f)
```

splits face f into triangles by inserting a new node u and connecting it to all nodes of f . Returns u .

list<edge> *M*.triangulate() triangulates all faces of *M* by inserting new edges.
The list of inserted edges is returned.

4. Implementation

Planar maps are implemented by parameterized directed graph. All operations take constant time, except for `new_edge` and `del_edge` which take time $O(f)$ where f is the number of edges in the created faces and `triangulate` and `straight_line_embedding` which take time $O(n)$ where n is the current size (number of edges) of the planar map.

- void* $M.assign(face\ f, const\ ftype\&\ x)$
 makes x the information of face f .
- edge* $M.new_edge(edge\ e1, edge\ e2, const\ ftype\&\ y)$
 inserts the edge $e = (source(e_1), source(e_2))$ and its reversal edge e' into M .
Precondition: e_1 and e_2 are bounding the same face F .
 The operation splits F into two new faces f , adjacent to edge e , and f' , adjacent to edge e' , with $inf(f) = inf(F)$ and $inf(f') = y$.
- edge* $M.split_edge(edge\ e, const\ vtype\&\ x)$
 splits edge $e = (v, w)$ and its reversal $r = (w, v)$ into edges (v, u) , (u, w) , (w, u) , and (u, v) . Assigns information x to the created node u and returns the edge (u, w) .
- node* $M.new_node(list<edge>\&\ el, const\ vtype\&\ x)$
 splits the face bounded by the edges in el by inserting a new node u and connecting it to all source nodes of edges in el . Assigns information x to u and returns u .
Precondition: all edges in el bound the same face.
- node* $M.new_node(face\ f, const\ vtype\&\ x)$
 splits face f into triangles by inserting a new node u with information x and connecting it to all nodes of f . Returns u .

4. Implementation

Parameterized planar maps are derived from planar maps. All additional operations for manipulating the node and edge contents take constant time.

12.8 Node Arrays (*node_array*)

1. Definition

An instance A of the parameterized data type *node_array* $\langle E \rangle$ is a partial mapping from the node set of a graph G to the set of variables of type E , called the element type of the array. The domain I of A is called the index set of A and $A(v)$ is called the element at position v . A is said to be valid for all nodes in I . The array access operator $A[v]$ checks its precondition (A must be valid for v). The check can be turned off by compiling with the flag `-DLEDA_CHECKING_OFF`.

```
#include <LEDA/graph/node_array.h >
```

2. Creation

node_array $\langle E \rangle$ A ; creates an instance A of type *node_array* $\langle E \rangle$ with empty index set.

node_array $\langle E \rangle$ $A(\text{const graph_t\&} G)$;
 creates an instance A of type *node_array* $\langle E \rangle$ and initializes the index set of A to the current node set of graph G .

node_array $\langle E \rangle$ $A(\text{const graph_t\&} G, E x)$;
 creates an instance A of type *node_array* $\langle E \rangle$, sets the index set of A to the current node set of graph G and initializes $A(v)$ with x for all nodes v of G .

node_array $\langle E \rangle$ $A(\text{const graph_t\&} G, \text{int } n, E x)$;
 creates an instance A of type *node_array* $\langle E \rangle$ valid for up to n nodes of graph G and initializes $A(v)$ with x for all nodes v of G .
Precondition: $n \geq |V|$.
 A is also valid for the next $n - |V|$ nodes added to G .

3. Operations

const graph_t\& $A.\text{get_graph}()$ returns a reference to the graph of A .

$E\&$ $A[\text{node } v]$ returns the variable $A(v)$.
Precondition: A must be valid for v .

void $A.\text{init}(\text{const graph_t\&} G)$ sets the index set I of A to the node set of G , i.e., makes A valid for all nodes of G .

void $A.\text{init}(\text{const graph_t\&} G, E x)$
 makes A valid for all nodes of G and sets $A(v) = x$ for all nodes v of G .

void *A*.init(*const graph_t& G*, *int n*, *E x*)

makes *A* valid for at most *n* nodes of *G* and sets $A(v) = x$ for all nodes *v* of *G*.

Precondition: $n \geq |V|$.

A is also valid for the next $n - |V|$ nodes added to *G*.

bool *A*.use_node_data(*const graph_t& G*)

use free data slots in the nodes of *G* (if available) for storing the entries of *A*. If no free data slot is available in *G*, an ordinary *node_array<E>* is created. The number of additional data slots in the nodes and edges of a graph can be specified in the *graph::graph(int n_slots, int e_slots)* constructor. The result is *true* if a free slot is available and *false* otherwise.

bool *A*.use_node_data(*const graph_t& G*, *E x*)

use free data slots in the nodes of *G* (if available) for storing the entries of *A* and initializes $A(v) = x$ for all nodes *v* of *G*. If no free data slot is available in *G*, an ordinary *node_array<E>* is created. The number of additional data slots in the nodes and edges of a graph can be specified in the *graph::graph(int n_slots, int e_slots)* constructor. The result is *true* if a free slot is available and *false* otherwise.

4. Implementation

Node arrays for a graph *G* are implemented by C++ vectors and an internal numbering of the nodes and edges of *G*. The access operation takes constant time, *init* takes time $O(n)$, where *n* is the number of nodes in *G*. The space requirement is $O(n)$.

Remark: A node array is only valid for a bounded number of nodes of *G*. This number is either the number of nodes of *G* at the moment of creation of the array or it is explicitly set by the user. Dynamic node arrays can be realized by node maps (cf. section 12.11).

12.9 Edge Arrays (*edge_array*)

1. Definition

An instance A of the parameterized data type $edge_array\langle E \rangle$ is a partial mapping from the edge set of a graph G to the set of variables of type E , called the element type of the array. The domain I of A is called the index set of A and $A(e)$ is called the element at position e . A is said to be valid for all edges in I . The array access operator $A[e]$ checks its precondition (A must be valid for e). The check can be turned off by compiling with the flag `-DLEDA_CHECKING_OFF`.

```
#include < LEDA/graph/edge_array.h >
```

2. Creation

$edge_array\langle E \rangle$ A ; creates an instance A of type $edge_array\langle E \rangle$ with empty index set.

$edge_array\langle E \rangle$ $A(const\ graph_t\&\ G)$;

creates an instance A of type $edge_array\langle E \rangle$ and initializes the index set of A to be the current edge set of graph G .

$edge_array\langle E \rangle$ $A(const\ graph_t\&\ G, E\ x)$;

creates an instance A of type $edge_array\langle E \rangle$, sets the index set of A to the current edge set of graph G and initializes $A(v)$ with x for all edges v of G .

$edge_array\langle E \rangle$ $A(const\ graph_t\&\ G, int\ n, E\ x)$;

creates an instance A of type $edge_array\langle E \rangle$ valid for up to n edges of graph G and initializes $A(e)$ with x for all edges e of G .

Precondition: $n \geq |E|$.

A is also valid for the next $n - |E|$ edges added to G .

3. Operations

$const\ graph_t\&$ $A.get_graph()$ returns a reference to the graph of A .

$E\&$ $A[edge\ e]$ returns the variable $A(e)$.

Precondition: A must be valid for e .

$void$ $A.init(const\ graph_t\&\ G)$ sets the index set I of A to the edge set of G , i.e., makes A valid for all edges of G .

$void$ $A.init(const\ graph_t\&\ G, E\ x)$

makes A valid for all edges of G and sets $A(e) = x$ for all edges e of G .

void `A.init(const graph_t& G, int n, E x)`

makes A valid for at most n edges of G and sets $A(e) = x$ for all edges e of G .

Precondition: $n \geq |E|$.

A is also valid for the next $n - |E|$ edges added to G .

bool `A.use_edge_data(const graph_t& G, E x)`

use free data slots in the edges of G (if available) for storing the entries of A . The number of additional data slots in the nodes and edges of a graph can be specified in the `graph::graph(int n_slots, int e_slots)` constructor. The result is *true* if a free slot is available and *false* otherwise.

4. Implementation

Edge arrays for a graph G are implemented by C++-vectors and an internal numbering of the nodes and edges of G . The access operation takes constant time, *init* takes time $O(n)$, where n is the number of edges in G . The space requirement is $O(n)$.

Remark: An edge array is only valid for a bounded number of edges of G . This number is either the number of edges of G at the moment of creation of the array or it is explicitly set by the user. Dynamic edge arrays can be realized by edge maps (cf. section 12.12).

12.10 Face Arrays (face_array)

1. Definition

An instance A of the parameterized data type $face_array\langle E \rangle$ is a partial mapping from the face set of a graph G to the set of variables of type E , called the element type of the array. The domain I of A is called the index set of A and $A(f)$ is called the element at position f . A is said to be valid for all faces in I . The array access operator $A[f]$ checks its precondition (A must be valid for f). The check can be turned off by compiling with the flag `-DLEDA_CHECKING_OFF`.

```
#include < LEDA/graph/face_array.h >
```

2. Creation

```
face_array<E> A;    creates an instance A of type face_array<E> with empty index set.
```

```
face_array<E> A(const graph_t& G);
                    creates an instance A of type face_array<E> and initializes the index
                    set of A to the current face set of graph G.
```

```
face_array<E> A(const graph_t& G, E x);
                    creates an instance A of type face_array<E>, sets the index set of
                    A to the current face set of graph G and initializes A(f) with x for
                    all faces f of G.
```

```
face_array<E> A(const graph_t& G, int n, E x);
                    creates an instance A of type face_array<E> valid for up to n faces
                    of graph G and initializes A(f) with x for all faces f of G.
                    Precondition:  $n \geq |V|$ .
                    A is also valid for the next  $n - |V|$  faces added to G.
```

3. Operations

```
const graph_t& A.get_graph()    returns a reference to the graph of A.
```

```
E& A[face f]                    returns the variable A(f).
                    Precondition: A must be valid for f.
```

```
void A.init(const graph_t& G)    sets the index set I of A to the face set of G, i.e., makes
                    A valid for all faces of G.
```

```
void A.init(const graph_t& G, E x)
                    makes A valid for all faces of G and sets A(f) = x for
                    all faces f of G.
```

void `A.init(const graph_t& G, int n, E x)`

makes A valid for at most n faces of G and sets $A(f) = x$ for all faces f of G .

Precondition: $n \geq |V|$.

A is also valid for the next $n - |V|$ faces added to G .

bool `A.use_face_data(const graph_t& G, E x)`

use free data slots in the faces of G (if available) for storing the entries of A . The number of additional data slots in the nodes and edges of a graph can be specified in the `graph::graph(int n_slots, int e_slots)` constructor. The result is *true* if a free slot is available and *false* otherwise.

4. Implementation

Node arrays for a graph G are implemented by C++vectors and an internal numbering of the faces and edges of G . The access operation takes constant time, *init* takes time $O(n)$, where n is the number of faces in G . The space requirement is $O(n)$.

Remark: A face array is only valid for a bounded number of faces of G . This number is either the number of faces of G at the moment of creation of the array or it is explicitly set by the user. Dynamic face arrays can be realized by face maps (cf. section 12.11).

12.11 Node Maps (*node_map*)

1. Definition

An instance of the data type *node_map*<*E*> is a map for the nodes of a graph *G*, i.e., equivalent to *map*<*node*, *E*> (cf. 8.4). It can be used as a dynamic variant of the data type *node_array* (cf. 12.8). **New:** Since *node_map*<*E*> is derived from *node_array*<*E*> node maps can be passed (by reference) to functions with node array parameters. In particular, all LEDA graph algorithms expecting a *node_array*<*E*>& argument can be passed a *node_map*<*E*> instead.

```
#include < LEDA/graph/node_map.h >
```

2. Creation

node_map<*E*> *M*; introduces a variable *M* of type *node_map*<*E*> and initializes it to the map with empty domain.

node_map<*E*> *M*(*const graph_t*& *G*);

introduces a variable *M* of type *node_map*<*E*> and initializes it with a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

node_map<*E*> *M*(*const graph_t*& *G*, *E* *x*);

introduces a variable *M* of type *node_map*<*E*> and initializes it with a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

3. Operations

const graph_t& *M*.get_graph() returns a reference to the graph of *M*.

void *M*.init() makes *M* a node map with empty domain.

void *M*.init(*const graph_t*& *G*)

makes *M* a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

void *M*.init(*const graph_t*& *G*, *E* *x*)

makes *M* a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

bool `M.use_node_data(const graph_t& G, E x)`

use free data slots in the nodes of G (if available) for storing the entries of A . The number of additional data slots in the nodes and edges of a graph can be specified in the `graph::graph(int n_slots, int e_slots)` constructor. The result is *true* if a free slot is available and *false* otherwise.

E& `M[node v]` returns the variable $M(v)$.

4. Implementation

Node maps either use free `node_slots` or they are implemented by an efficient hashing method based on the internal numbering of the nodes or they use. In each case an access operation takes expected time $O(1)$.

12.12 Edge Maps (*edge_map*)

1. Definition

An instance of the data type *edge_map*<*E*> is a map for the edges of a graph *G*, i.e., equivalent to *map*<*edge*, *E*> (cf. 8.4). It can be used as a dynamic variant of the data type *edge_array* (cf. 12.9). **New:** Since *edge_map*<*E*> is derived from *edge_array*<*E*> edge maps can be passed (by reference) to functions with edge array parameters. In particular, all LEDA graph algorithms expecting an *edge_array*<*E*>& argument can be passed an *edge_map*<*E*>& instead.

```
#include < LEDA/graph/edge_map.h >
```

2. Creation

edge_map<*E*> *M*; introduces a variable *M* of type *edge_map*<*E*> and initializes it to the map with empty domain.

edge_map<*E*> *M*(*const graph_t*& *G*);

introduces a variable *M* of type *edge_map*<*E*> and initializes it with a mapping *m* from the set of all edges of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

edge_map<*E*> *M*(*const graph_t*& *G*, *E* *x*);

introduces a variable *M* of type *edge_map*<*E*> and initializes it with a mapping *m* from the set of all edges of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

3. Operations

const graph_t& *M*.get_graph() returns a reference to the graph of *M*.

void *M*.init() makes *M* a edge map with empty domain.

void *M*.init(*const graph_t*& *G*)

makes *M* a mapping *m* from the set of all edges of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

void *M*.init(*const graph_t*& *G*, *E* *x*)

makes *M* a mapping *m* from the set of all edges of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

bool $M.use_edge_data(const\ graph_t\&\ G, E\ x)$

use free data slots in the edges of G (if available) for storing the entries of A . The number of additional data slots in the nodes and edges of a graph can be specified in the `graph::graph(int n_slots, int e_slots)` constructor. The result is *true* if a free slot is available and *false* otherwise.

E& $M[edge\ e]$ returns the variable $M(v)$.

4. Implementation

Edge maps are implemented by an efficient hashing method based on the internal numbering of the edges. An access operation takes expected time $O(1)$.

12.13 Face Maps (*face_map*)

1. Definition

An instance of the data type *face_map*<*E*> is a map for the faces of a graph *G*, i.e., equivalent to *map*<*face*, *E*> (cf. 8.4). It can be used as a dynamic variant of the data type *face_array* (cf. 12.10). **New:** Since *face_map*<*E*> is derived from *face_array*<*E*> face maps can be passed (by reference) to functions with face array parameters. In particular, all LEDA graph algorithms expecting a *face_array*<*E*>& argument can be passed a *face_map*<*E*> instead.

```
#include < LEDA/graph/face_map.h >
```

2. Creation

face_map<*E*> *M*; introduces a variable *M* of type *face_map*<*E*> and initializes it to the map with empty domain.

face_map<*E*> *M*(*const graph_t*& *G*);
 introduces a variable *M* of type *face_map*<*E*> and initializes it with a mapping *m* from the set of all faces of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

face_map<*E*> *M*(*const graph_t*& *G*, *E* *x*);
 introduces a variable *M* of type *face_map*<*E*> and initializes it with a mapping *m* from the set of all faces of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

3. Operations

const graph_t& *M*.get_graph() returns a reference to the graph of *M*.

void *M*.init() makes *M* a face map with empty domain.

void *M*.init(*const graph_t*& *G*)
 makes *M* a mapping *m* from the set of all faces of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

void *M*.init(*const graph_t*& *G*, *E* *x*)
 makes *M* a mapping *m* from the set of all faces of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

$E \& M[\textit{face } f]$ returns the variable $M(v)$.

4. Implementation

Face maps are implemented by an efficient hashing method based on the internal numbering of the faces. An access operation takes expected time $O(1)$.

12.14 Two Dimensional Node Arrays (*node_matrix*)

1. Definition

An instance M of the parameterized data type *node_matrix*< E > is a partial mapping from the set of node pairs $V \times V$ of a graph to the set of variables of data type E , called the element type of M . The domain I of M is called the index set of M . M is said to be valid for all node pairs in I . A node matrix can also be viewed as a node array with element type *node_array*< E > (*node_array*<*node_array*< E > >).

```
#include < LEDA/graph/node_matrix.h >
```

2. Creation

node_matrix< E > M ; creates an instance M of type *node_matrix*< E > and initializes the index set of M to the empty set.

node_matrix< E > M (*const graph_t*& G);

creates an instance M of type *node_matrix*< E > and initializes the index set to be the set of all node pairs of graph G , i.e., M is made valid for all pairs in $V \times V$ where V is the set of nodes currently contained in G .

node_matrix< E > M (*const graph_t*& G , E x);

creates an instance M of type *node_matrix*< E > and initializes the index set of M to be the set of all node pairs of graph G , i.e., M is made valid for all pairs in $V \times V$ where V is the set of nodes currently contained in G . In addition, $M(v, w)$ is initialized with x for all nodes $v, w \in V$.

3. Operations

void M .init(*const graph_t*& G)

sets the index set of M to $V \times V$, where V is the set of all nodes of G .

void M .init(*const graph_t*& G , E x)

sets the index set of M to $V \times V$, where V is the set of all nodes of G and initializes $M(v, w)$ to x for all $v, w \in V$.

const node_array< E >& M [*node* v] returns the *node_array* $M(v)$.

const E& M (*node* v , *node* w) returns the variable $M(v, w)$.

Precondition: M must be valid for v and w .

4. Implementation

Node matrices for a graph G are implemented by vectors of node arrays and an internal numbering of the nodes of G . The access operation takes constant time, the `init` operation takes time $O(n^2)$, where n is the number of nodes currently contained in G . The space requirement is $O(n^2)$. Note that a node matrix is only valid for the nodes contained in G at the moment of the matrix declaration or initialization (*init*). Access operations for later added nodes are not allowed.

12.15 Two-Dimensional Node Maps (*node_map2*)

1. Definition

An instance of the data type *node_map2*<*E*> is a map2 for the pairs of nodes of a graph *G*, i.e., equivalent to *map2*<*node*, *node*, *E*> (cf. 8.5). It can be used as a dynamic variant of the data type *node_matrix* (cf. 12.14).

```
#include < LEDA/graph/node_map2.h >
```

2. Creation

node_map2<*E*> *M*; introduces a variable *M* of type *node_map2*<*E*> and initializes it to the map2 with empty domain.

node_map2<*E*> *M*(*const graph_t*& *G*);

introduces a variable *M* of type *node_map2*<*E*> and initializes it with a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

node_map2<*E*> *M*(*const graph_t*& *G*, *E* *x*);

introduces a variable *M* of type *node_map2*<*E*> and initializes it with a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

3. Operations

void *M*.init() makes *M* a node map2 with empty domain.

void *M*.init(*const graph_t*& *G*)

makes *M* to a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized by a call of the default constructor of type *E*.

void *M*.init(*const graph_t*& *G*, *E* *x*)

makes *M* to a mapping *m* from the set of all nodes of *G* into the set of variables of type *E*. The variables in the range of *m* are initialized with a copy of *x*.

E& *M*(*node* *v*, *node* *w*) returns the variable *M*(*v*, *w*).

bool *M*.defined(*node* *v*, *node* *w*)

returns true if $(v, w) \in \text{dom}(M)$ and false otherwise.

4. Implementation

Node maps are implemented by an efficient hashing method based on the internal numbering of the nodes. An access operation takes expected time $O(1)$.

12.16 Sets of Nodes (*node_set*)

1. Definition

An instance S of the data type *node_set* is a subset of the nodes of a graph G . S is said to be valid for the nodes of G .

```
#include < LEDA/graph/node_set.h >
```

2. Creation

```
node_set  $S$ (const graph&  $G$ );
```

creates an instance S of type *node_set* valid for all nodes currently contained in graph G and initializes it to the empty set.

3. Operations

```
void  $S$ .insert(node  $x$ )      adds  $x$  to  $S$ .
```

```
void  $S$ .del(node  $x$ )        removes  $x$  from  $S$ .
```

```
bool  $S$ .member(node  $x$ )    returns true if  $x$  in  $S$ , false otherwise.
```

```
node  $S$ .choose()            returns a node of  $S$ .
```

```
int  $S$ .size()                returns the size of  $S$ .
```

```
bool  $S$ .empty()             returns true iff  $S$  is the empty set.
```

```
void  $S$ .clear()             makes  $S$  the empty set.
```

4. Implementation

A node set S for a graph G is implemented by a combination of a list L of nodes and a node array of `list_items` associating with each node its position in L . All operations take constant time, except for `clear` which takes time $O(S)$. The space requirement is $O(n)$, where n is the number of nodes of G .

12.17 Sets of Edges (`edge_set`)

1. Definition

An instance S of the data type `edge_set` is a subset of the edges of a graph G . S is said to be valid for the edges of G .

```
#include < LEDA/graph/edge_set.h >
```

2. Creation

```
edge_set S(const graph& G);
```

creates an instance S of type `edge_set` valid for all edges currently in graph G and initializes it to the empty set.

3. Operations

```
void S.insert(edge x)      adds edge  $x$  to  $S$ .
```

```
void S.del(edge x)        removes edge  $x$  from  $S$ .
```

```
bool S.member(edge x)    returns true if  $x$  in  $S$ , false otherwise.
```

```
edge S.choose()          returns an edge of  $S$ .
```

```
int S.size()             returns the size of  $S$ .
```

```
bool S.empty()          returns true iff  $S$  is the empty set.
```

```
void S.clear()          makes  $S$  the empty set.
```

4. Implementation

An edge set S for a graph G is implemented by a combination of a list L of edges and an edge array of `list_items` associating with each edge its position in L . All operations take constant time, except for `clear` which takes time $O(S)$. The space requirement is $O(n)$, where n is the number of edges of G .

12.18 Lists of Nodes (*node_list*)

1. Definition

An instance of the data type *node_list* is a doubly linked list of nodes. It is implemented more efficiently than the general list type *list<node>* (7.7). However, it can only be used with the restriction that every node is contained in at most one *node_list*. Also many operations supported by *list<node>* (for instance *size*) are not supported by *node_list*.

```
#include <LEDA/graph/node_list.h >
```

2. Creation

node_list *L*; introduces a variable *L* of type *node_list* and initializes it with the empty list.

3. Operations

<i>void</i>	<i>L.append(node v)</i>	appends <i>v</i> to list <i>L</i> .
<i>void</i>	<i>L.push(node v)</i>	adds <i>v</i> at the front of <i>L</i> .
<i>void</i>	<i>L.insert(node v, node w)</i>	inserts <i>v</i> after <i>w</i> into <i>L</i> . <i>Precondition: w</i> ∈ <i>L</i> .
<i>node</i>	<i>L.pop()</i>	deletes the first node from <i>L</i> and returns it. <i>Precondition: L</i> is not empty.
<i>node</i>	<i>L.pop_back()</i>	deletes the last node from <i>L</i> and returns it. <i>Precondition: L</i> is not empty.
<i>void</i>	<i>L.del(node v)</i>	deletes <i>v</i> from <i>L</i> . <i>Precondition: v</i> ∈ <i>L</i> .
<i>bool</i>	<i>L.member(node v)</i>	returns true if <i>v</i> ∈ <i>L</i> and false otherwise.
<i>bool</i>	<i>L(node v)</i>	returns true if <i>v</i> ∈ <i>L</i> and false otherwise.
<i>node</i>	<i>L.head()</i>	returns the first node in <i>L</i> (nil if <i>L</i> is empty).
<i>node</i>	<i>L.tail()</i>	returns the last node in <i>L</i> (nil if <i>L</i> is empty).
<i>node</i>	<i>L.succ(node v)</i>	returns the successor of <i>v</i> in <i>L</i> . <i>Precondition: v</i> ∈ <i>L</i> .
<i>node</i>	<i>L.pred(node v)</i>	returns the predecessor of <i>v</i> in <i>L</i> . <i>Precondition: v</i> ∈ <i>L</i> .
<i>node</i>	<i>L.cyclic_succ(node v)</i>	returns the cyclic successor of <i>v</i> in <i>L</i> . <i>Precondition: v</i> ∈ <i>L</i> .

<i>node</i>	$L.\text{cyclic_pred}(\textit{node } v)$	returns the cyclic predecessor of v in L . <i>Precondition:</i> $v \in L$.
<i>bool</i>	$L.\text{empty}()$	returns <i>true</i> if L is empty and <i>false</i> otherwise.
<i>void</i>	$L.\text{clear}()$	makes L the empty list.

forall(x, L) { “the elements of L are successively assigned to x ” }

12.19 Node Partitions (*node_partition*)

1. Definition

An instance P of the data type *node_partition* is a partition of the nodes of a graph G .

```
#include < LEDA/graph/node_partition.h >
```

2. Creation

```
node_partition P(const graph&  $G$ );
```

creates a *node_partition* P containing for every node v in G a block $\{v\}$.

3. Operations

```
int P.same_block(node  $v$ , node  $w$ )
```

returns positive integer if v and w belong to the same block of P , 0 otherwise.

```
void P.union_blocks(node  $v$ , node  $w$ )
```

unites the blocks of P containing nodes v and w .

```
void P.split(const list<node>&  $L$ )
```

makes all nodes in L to singleton blocks.

Precondition: L is a union of blocks.

```
node P.find(node  $v$ )
```

returns a canonical representative node of the block that contains node v .

```
void P.make_rep(node  $v$ )
```

makes v the canonical representative of the block containing v .

```
int P.size(node  $v$ )
```

returns the size of the block that contains node v .

```
int P.number_of_blocks()
```

returns the number of blocks of P .

```
node P(node  $v$ )
```

returns $P.find(v)$.

4. Implementation

A node partition for a graph G is implemented by a combination of a partition P and a node array of *partition_item* associating with each node in G a partition item in P . Initialization takes linear time, *union_blocks* takes time $O(1)$ (worst-case), and *same_block* and *find* take time $O(\alpha(n))$ (amortized). The cost of a split is proportional to the cost of the blocks dismantled. The space requirement is $O(n)$, where n is the number of nodes of G .

12.20 Node Priority Queues (`node_pq`)

1. Definition

An instance Q of the parameterized data type `node_pq<P>` is a partial function from the nodes of a graph G to a linearly ordered type P of priorities. The priority of a node is sometimes called the information of the node. For every graph G only one `node_pq<P>` may be used and every node of G may be contained in the queue at most once (cf. section 9.1 for general priority queues).

```
#include < LEDA/graph/node_pq.h >
```

2. Creation

```
node_pq<P> Q(const graph_t& G);
```

creates an instance Q of type `node_pq<P>` for the nodes of graph G with $dom(Q) = \emptyset$.

3. Operations

```
void Q.insert(node v, const P& x)
```

adds the node v with priority x to Q .
Precondition: $v \notin dom(Q)$.

```
const P& Q.prio(node v)
```

returns the priority of node v .
Precondition: $v \in dom(Q)$.

```
bool Q.member(node v)
```

returns true if v in Q , false otherwise.

```
void Q.decrease_p(node v, const P& x)
```

makes x the new priority of node v .
Precondition: $x \leq Q.prio(v)$.

```
node Q.find_min()
```

returns a node with minimal priority (nil if Q is empty).

```
void Q.del(node v)
```

removes the node v from Q .

```
node Q.del_min()
```

removes a node with minimal priority from Q and returns it (nil if Q is empty).

```
node Q.del_min(P& x)
```

as above, in addition the priority of the removed node is assigned to x .

```
void Q.clear()
```

makes Q the empty node priority queue.

```
int Q.size()
```

returns $|dom(Q)|$.

int `Q.empty()` returns positive integer if Q is the empty node priority queue, 0 otherwise.

const P& `Q.inf(node v)` returns the priority of node v .

4. Implementation

Node priority queues are implemented by binary heaps and node arrays. Operations `insert`, `del_node`, `del_min`, `decrease_p` take time $O(\log m)$, `find_min` and `empty` take time $O(1)$ and `clear` takes time $O(m)$, where m is the size of Q . The space requirement is $O(n)$, where n is the number of nodes of G .

12.21 Bounded Node Priority Queues (`b_node_pq`)

1. Definition

An instance of the data type `b_node_pq<N>` is a priority queue of nodes with integer priorities with the restriction that the size of the minimal interval containing all priorities in the queue is bounded by N , the sequence of the priorities of the results of calls of the method `del_min` is monotone increasing, and every node is contained in at most one queue. When applied to the empty queue the `del_min` - operation returns a special default minimum node defined in the constructor of the queue.

```
#include < LEDA/graph/b_node_pq.h >
```

2. Creation

`b_node_pq<N> PQ;` introduces a variable `PQ` of type `b_node_pq<N>` and initializes it with the empty queue with default minimum node `nil`.

`b_node_pq<N> PQ(node v);`
introduces a variable `PQ` of type `b_node_pq<N>` and initializes it with the empty queue with default minimum node `v`.

3. Operations

`node PQ.del_min()` removes the node with minimal priority from `PQ` and returns it (the default minimum node if `PQ` is empty).

`void PQ.insert(node w, int p)` adds node `w` with priority `p` to `PQ`.

`void PQ.del(node w, int = 0)` deletes node `w` from `PQ`.

4. Implementation

Bounded node priority queues are implemented by cyclic arrays of doubly linked node lists.

5. Example

Using a `b_node_pq` in Dijkstra's shortest paths algorithm.

```
int dijkstra(const GRAPH<int,int>& g, node s, node t)
{ node_array<int> dist(g,MAXINT);
  b_node_pq<100> PQ(t); // on empty queue del_min returns t
  dist[s] = 0;
```

```
for (node v = s; v != t; v = PQ.del_min() )
{ int dv = dist[v];
  edge e;
  forall_adj_edges(e,v)
  { node w = g.opposite(v,e);
    int d = dv + g.inf(e);
    if (d < dist[w])
    { if (dist[w] != MAXINT) PQ.del(w);
      dist[w] = d;
      PQ.insert(w,d);
    }
  }
}
return dist[t];
}
```

- void** **random_bigraph**(*graph& G*, *int a*, *int b*, *int m*, *list<node>& A*,
list<node>& B, *int k = 1*)
 creates a random bipartite graph G with a nodes on side A , b nodes on side B , and m edges. All edges are directed from A to B .
 If $k > 1$ then A and B are divided into k groups of about equal size and the nodes in the i -th group of A have their edges to nodes in the $i - 1$ -th and $i + 1$ -th group in B . All indices are modulo k .
- void** **test_bigraph**(*graph& G*, *list<node>& A*, *list<node>& B*)
 creates interactively a user defined bipartite graph G with sides A and B . All edges are directed from A to B .
- void** **grid_graph**(*graph& G*, *int n*)
 creates a grid graph G with $n \times n$ nodes.
- void** **grid_graph**(*graph& G*, *node_array<double>& xcoord*,
node_array<double>& ycoord, *int n*)
 creates a grid graph G of size $n \times n$ embedded into the unit square. The embedding is given by $xcoord[v]$ and $ycoord[v]$ for every node v of G .
- void** **d3_grid_graph**(*graph& G*, *int n*)
 creates a three-dimensional grid graph G with $n \times n \times n$ nodes.
- void** **d3_grid_graph**(*graph& G*, *node_array<double>& xcoord*,
node_array<double>& ycoord, *node_array<double>& zcoord*,
int n)
 creates a three-dimensional grid graph G of size $n \times n \times n$ embedded into the unit cube. The embedding is given by $xcoord[v]$, $ycoord[v]$, and $zcoord[v]$ for every node v of G .
- void** **cmdline_graph**(*graph& G*, *int argc*, *char **argv*)
 builds graph G as specified by the command line arguments:

	<code>prog</code>	<code>→</code>	<code>test_graph()</code>
guments:	<code>prog n</code>	<code>→</code>	<code>complete_graph(n)</code>
	<code>prog n m</code>	<code>→</code>	<code>test_graph(n, m)</code>
	<code>prog file</code>	<code>→</code>	<code>G.read_graph(file)</code>

Planar graph: Combinatorial Constructions

A maximal planar map with n nodes, $n \geq 3$, has $3n - 6$ uedges. It is constructed iteratively. For $n = 1$, the graph consists of a single isolated node, for $n = 2$, the graph consists of two nodes and one uedge, for $n = 3$ the graph consists of three nodes and three

uedges. For $n > 3$, a random maximal planar map with $n - 1$ nodes is constructed first and then an additional node is put into a random face.

The generator with the additional parameter m first generates a maximal planar map and then deletes all but m edges.

The generators with the word map replaced by graph, first generate a map and then delete one edge from each uedge.

```
void          maximal_planar_map(graph& G, int n)
                                creates a maximal planar map G with n nodes.

void          random_planar_map(graph& G, int n, int m)
                                creates a random planar map G with n nodes and m
                                edges.

void          maximal_planar_graph(graph& G, int n)
                                creates a maximal planar graph G with n nodes.

void          random_planar_graph(graph& G, int n, int m)
                                creates a random planar graph G with n nodes and m
                                edges.
```

Planar graph: Geometric Constructions

We have two kinds of geometric constructions: triangulations of point sets and intersection graph of line segments. The functions *triangulation_map* choose points in the unit square and compute a triangulation of them and the functions *random_planar_graph* construct the intersection graph of segments.

The generators with the word map replaced by graph, first generate a map and then delete one edge from each uedge.

```
void          triangulation_map(graph& G, node_array<double>& xcoord,
                                node_array<double>& ycoord, int n)
                                chooses n random points in the unit square and re-
                                turns their triangulation as a plane map in G. The
                                coordinates of node v are returned as xcoord[v] and
                                ycoord[v]. The coordinates are random number of the
                                form  $x/K$  where  $K = 2^{20}$  and  $x$  is a random integer
                                between 0 (inclusive) and  $K$  (exclusive).

void          triangulation_map(graph& G, list<node>& outer_face,
                                node_array<double>& xcoord,
                                node_array<double>& ycoord, int n)
                                as above, in addition the list of nodes of the outer face
                                ( convex hull) is returned in outer_face in clockwise
                                order.
```

- void* `triangulation_map(graph& G, int n)`
 as above, but only the map is returned.
- void* `random_planar_map(graph& G, node_array<double>& xcoord,`
 `node_array<double>& ycoord, int n, int m)`
 chooses n random points in the unit square and computes their triangulation as a plane map in G . It then keeps all but m uedges. The coordinates of node v are returned as `xcoord[v]` and `ycoord[v]`.
- void* `triangulation_graph(graph& G, node_array<double>& xcoord,`
 `node_array<double>& ycoord, int n)`
 calls `triangulation_map` and keeps only one of the edges comprising a uedge.
- void* `triangulation_graph(graph& G, list<node>& outer_face,`
 `node_array<double>& xcoord,`
 `node_array<double>& ycoord, int n)`
 calls `triangulation_map` and keeps only one of the edges comprising a uedge.
- void* `triangulation_graph(graph& G, int n)`
 calls `triangulation_map` and keeps only one of the edges comprising a uedge.
- void* `random_planar_graph(graph& G, node_array<double>& xcoord,`
 `node_array<double>& ycoord, int n, int m)`
 calls `random_planar_map` and keeps only one of the edges comprising a uedge.
- void* `triangulated_planar_graph(graph& G, int n)`
 old name for `triangulation_graph`.
- void* `triangulated_planar_graph(graph& G, node_array<double>& xcoord,`
 `node_array<double>& ycoord, int n)`
 old name for `triangulation_graph`.
- void* `triangulated_planar_graph(graph& G, list<node>& outer_face,`
 `node_array<double>& xcoord,`
 `node_array<double>& ycoord, int n)`
 old name for `triangulation_graph`.

void `random_planar_graph(graph& G, node_array<double>& xcoord,`
 `node_array<double>& ycoord, int n)`
 creates a random planar graph G with n nodes embedded into the unit square. The embedding is given by $xcoord[v]$ and $ycoord[v]$ for every node v of G . The generator chooses n segments whose endpoints have random coordinates of the form x/K , where K is the smallest power of two greater or equal to n , and x is a random integer in 0 to $K - 1$. It then constructs the arrangement defined by the segments and keeps the n nodes with the smallest x -coordinates. Finally, it adds edges to make the graph connected.

void `random_planar_graph(graph& G, int n)`
 creates a random planar graph G with n nodes. Uses the preceding function.

Series-Parallel Graphs

void `random_sp_graph(graph& G, int n, int m)`
 creates a random series-parallel graph G with n nodes and m edges.

12.23 Miscellaneous Graph Functions (graph_misc)

1. Operations

#include < LEDA/graph/graph_misc.h >

void CopyGraph(*graph*& *H*, *const graph*& *G*)

constructs a copy *H* of graph *G*.

void CopyGraph(*GRAPH*<*node*, *edge*>& *H*, *const graph*& *G*)

constructs a copy *H* of graph *G* such that *H*[*v*] is the node of *G* that corresponds to *v* and *H*[*e*] is the edge of *G* that corresponds to *e*.

void CopyGraph(*GRAPH*<*node*, *edge*>& *H*, *const graph*& *G*,
const list<*node*>& *V*, *const list*<*edge*>& *E*)

constructs a copy *H* of the subgraph (*V*, *E*) of *G* such that *H*[*v*] is the node of *G* that corresponds to *v* and *H*[*e*] is the edge of *G* that corresponds to *e*. *Precondition*: *V* is a subset of the nodes of *G* and *E* is a subset of $V \times V$.

void CopyGraph(*GRAPH*<*node*, *edge*>& *H*, *const graph*& *G*,
const list<*edge*>& *E*)

constructs a copy *H* of the subgraph of *G* induced by the edges in *E*.

bool IsSimple(*const graph*& *G*) returns true if *G* is simple, i.e., has no parallel edges, false otherwise.

bool IsSimple(*const graph*& *G*, *list*<*edge*>& *el*)

as above, but returns in addition the list of all edges sorted lexicographically by source and target node, i.e, all parallel edges appear consecutively in *el*.

bool IsLoopfree(*const graph*& *G*)

returns true if *G* is loopfree, i.e., has no edge whose source is equal to its target.

bool IsSimpleLoopfree(*const graph*& *G*)

returns true if *G* is simple and loopfree.

bool IsUndirectedSimple(*const graph*& *G*)

returns true if *G* viewed as an undirected graph is simple, i.e., *G* is loopfree, simple, and has no anti-parallel edges.

- bool* `IsBidirected(const graph& G)`
returns true if every edge has a reversal and false otherwise.
- bool* `IsBidirected(const graph& G, edge_array<edge>& rev)`
computes for every edge $e = (v, w)$ in G its reversal $rev[e] = (w, v)$ in G (nil if not present). Returns true if every edge has a reversal and false otherwise.
- bool* `IsMap(const graph& G)` tests whether G is a map.
- int* `Genus(const graph& G)` computes the genus of G .
Precondition: G must be a map.
- bool* `IsPlane_Map(const graph& G)`
tests whether G is a plane map, i.e, whether G is a map of genus zero.
- bool* `IsPlanar_Map(const graph& G)`
old name for `IsPlane_Map`
- bool* `IsAcyclic(const graph& G)`
returns true if the directed G is acyclic and false otherwise.
- bool* `IsAcyclic(const graph& G, list<edge>& L)`
as above; in addition, constructs a list of edges L whose deletion makes G acyclic.
- bool* `IsConnected(const graph& G)`
returns true if the undirected graph underlying G is connected and false otherwise.
- bool* `IsBiconnected(const graph& G)`
returns true if the undirected graph underlying G is biconnected and false otherwise.
- bool* `IsBiconnected(const graph& G, node& s)`
as above, computes a split vertex s if the result is *false*.
- bool* `IsTriconnected(const graph& G)`
returns true if the undirected graph underlying G is triconnected and false otherwise. The running time is $O(n(n + m))$.

- bool* `IsTriconnected(const graph& G, node& s1, node& s2)`
as above, computes a split pair s_1, s_2 if the result is *false*.
- bool* `IsBipartite(const graph& G)`
returns true if G is bipartite and false otherwise.
- bool* `IsBipartite(const graph& G, list<node>& A, list<node>& B)`
returns true if G is bipartite and false otherwise. If G is bipartite the two sides are returned in A and B , respectively. If G is not bipartite the node sequence of an odd-length circle is returned in A .
- bool* `IsPlanar(const graph& G)` returns true if G is planar and false otherwise.
- bool* `IsSeriesParallel(const graph& G)`
returns true if G is series-parallel and false otherwise.
- void* `MakeAcyclic(graph& G)` makes G acyclic by removing all DFS back edges.
- list<edge>* `MakeSimple(graph& G)` makes G simple by removing all but one from each set of parallel edges. Returns the list of remaining edges with parallel edges in the original graph.
- void* `MakeBidirected(graph& G, list<edge>& L)`
makes G bidirected by inserting missing reversal edges. Appends all inserted edges to list L .
- list<edge>* `MakeBidirected(graph& G)`
makes G bidirected by inserting missing reversal edges. Returns the list of inserted edges.
- void* `MakeConnected(graph& G, list<edge>& L)`
makes G connected; appends all inserted edges to list L .
- list<edge>* `MakeConnected(graph& G)`
makes G connected; returns the list of inserted edges.
- void* `MakeBiconnected(graph& G, list<edge>& L)`
makes G biconnected; appends all inserted edges to list L .
- list<edge>* `MakeBiconnected(graph& G)`
makes G biconnected; returns the list of inserted edges.

list<node> DeleteLoops(*graph& G*) returns the list of nodes with self-loops and deletes all self-loops.

12.24 Markov Chains (markov_chain)

1. Definition

We consider a Markov Chain to be a graph G in which each edge has an associated non-negative integer weight $w[e]$. For every node (with at least one outgoing edge) the total weight of the outgoing edges must be positive. A random walk in a Markov chain starts at some node s and then performs steps according to the following rule:

Initially, s is the current node. Suppose node v is the current node and that e_0, \dots, e_{d-1} are the edges out of v . If v has no outgoing edge no further step can be taken. Otherwise, the walk follows edge e_i with probability proportional to $w[e_i]$ for all i , $0 \leq i < d$. The target node of the chosen edge becomes the new current node.

```
#include < LEDA/graph/markov_chain.h >
```

2. Creation

```
markov_chain M(const graph& G, const edge_array<int>& w, node s = nil);
```

creates a Markov chain for the graph G with edge weights w . The node s is taken as the start vertex ($G.first_node()$ if s is nil).

3. Operations

```
void M.step(int T = 1) performs T steps of the Markov chain.
```

```
node M.current_node() returns current vertex.
```

```
int M.current_outdeg() returns the outdegree of the current vertex.
```

```
int M.number_of_steps() returns number of steps performed.
```

```
int M.number_of_visits(node v)
```

returns number of visits to node v .

```
double M.rel_freq_of_visit(node v)
```

returns number of visits divided by the total number of steps.

12.25 Dynamic Markov Chains (`dynamic_markov_chain`)

1. Definition

A Markov Chain is a graph G in which each edge has an associated non-negative integer weight $w[e]$. For every node (with at least one outgoing edge) the total weight of the outgoing edges must be positive. A random walk in a Markov chain starts at some node s and then performs steps according to the following rule:

Initially, s is the current node. Suppose node v is the current node and that e_0, \dots, e_{d-1} are the edges out of v . If v has no outgoing edge no further step can be taken. Otherwise, the walk follows edge e_i with probability proportional to $w[e_i]$ for all i , $0 \leq i < d$. The target node of the chosen edge becomes the new current node.

```
#include < LEDA/graph/markov_chain.h >
```

2. Creation

```
dynamic_markov_chain M(const graph& G, const edge_array<int>& w, node s = nil);
```

creates a Markov chain for the graph G with edge weights w . The node s is taken as the start vertex ($G.first_node()$ if s is nil).

3. Operations

```
void M.step(int T = 1) performs T steps of the Markov chain.
```

```
node M.current_node() returns current vertex.
```

```
int M.current_outdeg() returns the outdegree of the current vertex.
```

```
int M.number_of_steps() returns number of steps performed.
```

```
int M.number_of_visits(node v)
```

returns number of visits to node v .

```
double M.rel_freq_of_visit(node v)
```

returns number of visits divided by the total number of steps.

```
int M.set_weight(edge e, int g)
```

changes the weight of edge e to g and returns the old weight of e

12.26 GML Parser for Graphs (gml_graph)

1. Definition

An instance *parser* of the data type *gml_graph* is a parser for graph in GML format [46]. It is possible to extend the parser by user defined rules. This parser is used by the *read_gml* of class *graph*. The following is a small example graph (a triangle) in GML format.

```
# This is a comment.
graph [          # Lists start with '['.
  directed 1    # This is a directed graph (0 for undirected).

  # The following is an object of type string.
  # It will be ignored unless you specify a rule for graph.text.
  text "This is a string object."

  node [ id 1 ] # This defines a node with id 1.
  node [ id 2 ]
  node [ id 3 ]

  edge [ # This defines an edge leading from node 1 to node 2.
    source 1
    target 2
  ]
  edge [
    source 2
    target 3
  ]
  edge [
    source 3
    target 1
  ]
] # Lists end with ']'.
```

An input in GML format is a list of GML objects. Each object consists of a key word and a value. A value may have one out of four possible types, an integer (type *gml_int*), a double (type *gml_double*), a string (type *gml_string*), or a list of GML objects (type *gml_list*). Since a value can be a list of objects, we get a tree structure on the input. We can describe a class *C* of objects being in the same list and having the same key word by the so-called path. The path is the list of key words leading to an object in the class *C*.

In principle, every data structure can be expressed in GML format. This parser specializes on graphs. A graph is represented by an object with key word *graph* and type *gml_list*. The nodes of the graph are objects with path *graph.node* and type *gml_list*. Each node has a unique identifier, which is represented by an object of type *gml_int* with path *graph.node.id*. An edge is an object of type *gml_list* with the path *graph.edge*. Each edge

has a source and a target. These are objects of type *gml_int* with path *graph.edge.source* and *graph.edge.target*, respectively. The integer values of *source* and *target* refer to node identifiers. There are some global graph attributes, too. An object of type *gml_int* with path *graph.directed* determines whether the graph is undirected (value 0) or directed (every other integer). The type of node parameters and edge parameters in parameterized graph (see manual page GRAPH) can be given by objects of type *gml_string* with path *graph.nodeType* and *graph.edgeType*, respectively. Parameters of nodes and edges are represented by objects of type *gml_string* with path *graph.node.parameter* and *graph.edge.parameter*, respectively.

No list has to be in a specific order, e.g., you can freely mix *node* and *edge* objects in the *graph* list. If there are several objects in a class where just one object is required like *graph.node.id*, only the last such object is taken into account.

Objects in classes with no predefined rules are simply ignored. This means that an application *A* might add specific objects to a graph description in GML format and this description is still readable for another application *B* which simply does not care about the objects which are specific for *A*.

This parser supports reading user defined objects by providing a mechanism for dealing with those objects by means of callback functions. You can specify a rule for, e.g., objects with path *graph.node.weight* and type *gml_double* like in the following code fragment.

```

...
bool get_node_weight(const gml_object* gobj, graph* G, node v)
{
    double w = gobj->get_double();
    do something with w, the graph and the corresponding node v
    return true; or false if the operation failed
}
...
main()
{
    char* filename;
    ...
    graph G;
    gml_graph parser(G);
    parser.append("graph"); parser.append("node");
    parser.append("weight");
    parser.add_node_rule_for_cur_path(get_node_weight, gml_double);
    // or short parser.add_node_rule(get_node_weight, gml_double, "weight");
    bool parsing_ok = parser.parse(filename);
    ...
}

```

You can add rules for the graph, for nodes, and for edges. The difference between them is the type. The type of node rules is as in the example above

`bool (*gml_node_rule)(const gml_object*, graph*, node)`, the type for edge rules is `bool (*gml_edge_rule)(const gml_object*, graph*, edge)`, and the type for graph rules is `bool (*gml_graph_rule)(const gml_object*, graph*)`. A GML object is represented by an instance of class `gml_object`. You can get its value by using `double gml_object::get_double()`, `int gml_object::get_int()` or `char* gml_object::get_string()`. If one of your rules returns *false* during parsing, then parsing fails and the graph is cleared.

```
#include < LEDA/graph/gml_graph.h >
```

2. Creation

```
gml_graph parser(graph& G);
```

creates an instance *parser* of type *gml_graph* and initializes it for *graph G*.

```
gml_graph parser(graph& G, const char * filename);
```

creates an instance *parser* of type *gml_graph* and reads *graph G* from the file *filename*.

```
gml_graph parser(graph& G, istream& ins);
```

creates an instance *parser* of type *gml_graph* and reads *graph G* from the input stream *ins*.

3. Operations

3.1 Parsing

```
bool parser.parse(const char * filename)
```

parses the input taken from the file *filename* using the current set of rules. The graph specified in the constructor is set up accordingly. This operation returns *false* and clears the graph, if syntax or parse errors occur. Otherwise *true* is returned.

```
bool parser.parse(istream& ins)
```

parses the input taken from the input stream *ins*.

```
bool parser.parse_string(string s)
```

parses the input taken from string *s*.

3.2 Path Manipulation

```
void parser.reset_path() resets the current path to the empty path.
```

```
void parser.append(const char * key)
```

appends *key* to the current path.

void parser.goBack() removes the last key word from the current path. If the current path is empty this operation has no effect.

3.3 User Defined Rules

void parser.add_graph_rule_for_cur_path(gml_graph_rule f, gml_value_type t)
adds graph rule *f* for value type *t* and for the current path.

void parser.add_node_rule_for_cur_path(gml_node_rule f, gml_value_type t)
adds node rule *f* for value type *t* and for the current path.

void parser.add_edge_rule_for_cur_path(gml_edge_rule f, gml_value_type t)
adds edge rule *f* for value type *t* and for the current path.

*void parser.add_graph_rule(gml_graph_rule f, gml_value_type t, char * key = 0)*
adds graph rule *f* for value type *t* and path *graph.key* to *parser*, if key is specified. Otherwise, *f* is added for the current path.

*void parser.add_node_rule(gml_node_rule f, gml_value_type t, char * key = 0)*
adds node rule *f* for path *graph.node.key* (or the current path, if no key is specified) and value type *t* to *parser*.

*void parser.add_edge_rule(gml_edge_rule f, gml_value_type t, char * key = 0)*
adds edge rule *f* for path *graph.edge.key* (or the current path, if no key is specified) and value type *t* to *parser*.

void parser.add_new_graph_rule(gml_graph_rule f)
adds graph rule *f* to *parser*. During parsing *f* is called whenever an object *o* with path *graph* and type *gml_list* is encountered. *f* is called before objects in the list of *o* are parsed.

void parser.add_new_node_rule(gml_node_rule f)
adds node rule *f* for path *graph.node* and value type *gml_list* to *parser*. *f* is called before objects in the corresponding list are parsed.

void parser.add_new_edge_rule(gml_edge_rule f)
adds edge rule *f* for path *graph.edge* and value type *gml_list* to *parser*. *f* is called before objects in the corresponding list are parsed.

void parser.add_graph_done_rule(gml_graph_rule f)
adds graph rule *f* to *parser*. During parsing *f* is called whenever an object *o* with path *graph* and type *gml_list* is encountered. *f* is called after all objects in the list of *o* are parsed.

void parser.addNodeDoneRule(gml_node_rule f)

adds node rule *f* to *parser* for path *graph.node* and value type *gml_list*. *f* is called after all objects in the corresponding list are parsed.

void parser.addEdgeDoneRule(gml_edge_rule f)

adds edge rule *f* to *parser* for path *graph.edge* and value type *gml_list*. *f* is called after all objects in the corresponding list are parsed.

4. Implementation

The data type *gml_graph* is realized using lists and maps. It inherits from *gml_parser* which uses *gml_object*, *gml_objecttree*, and *gml_pattern*. *gml_pattern* uses dictionaries.

12.27 The LEDA graph input/output format

The following passage describes the format of the output produced by the function `graph::write(ostream& out)`. The output consists of several lines which are separated by `endl`. Comment-lines have a `#` character in the first column and are ignored. The output can be partitioned in three sections:

Header Section

The first line always contains the string `LEDA.GRAPH`. If the graph type is not parameterized, i.e. `graph` or `ugraph`, the following two lines both contain the string `void`. In case the graph is parameterized, i.e. `GRAPH` or `UGRAPH`, these lines contain a description of the node type and the edge type, which is obtained by calling the macro `LEDA_TYPE_NAME`. The fourth line specifies if the graph is either directed (-1) or undirected (-2).

Nodes Section

The first line contains `n`, the number of nodes in the graph. The nodes are ordered and numbered according to their position in the node list of the graph. Each of the following `n` lines contains the information which is associated with the respective node of the graph. When the information of a node (or an edge) is sent to an output stream, it is always enclosed by the strings `{` and `}`. If the graph is not parameterized, then the string between these parantheses is empty, so that all the `n` lines contain the string `{ }`.

Edges Section

The first line contains `m`, the number of edges in the graph. The edges of the graph are ordered by two criteria: first according to the number of their source node and second according to their position in the adjacency list of the source node. Each of the next `m` lines contains the description of an edge which consists of four space-separated parts:

- (a) the number of the source node
- (b) the number of the target node
- (c) the number of the reversal edge or 0, if no such edge is set
- (d) the information associated with the edge (cf. nodes section)

Note: For the data type `planar_map` the order of the edges is important, because the ordering of the edges in the adjacency list of a node corresponds to the counter-clockwise ordering of these edges around the node in the planar embedding. And the information about reversal edges is also vital for this data type.

Chapter 13

Graph Algorithms

This chapter gives a summary of the graph algorithms contained in LEDA, basic graph algorithms for reachability problems, shortest path algorithms, matching algorithms, flow algorithms,

All graph algorithms are generic, i.e., they accept instances of any user defined parameterized graph type *GRAPH*<*vtype*, *etype*> as arguments.

All graph algorithms are available by including the header file <LEDA/graph/graph_alg.h>. Alternatively, one may include a more specific header file.

An important subclass of graph algorithms are network algorithms. The input to most network algorithms is a graph whose edges or nodes are labeled with numbers, e.g., shortest path algorithms get edge costs, network flow algorithms get edge capacities, and min cost flow algorithms get edge capacities and edge costs. We use *NT* to denote the number type used for the edge and node labels.

Most network algorithms come in three kinds: A templated version in which *NT* is a template parameter, and instantiated and precompiled versions for the number types *int* (always) and *double* (except for a small number of functions). The function name of the templated version ends in *_T*. Thus *MAX_FLOW_T* is the name of the templated version of the max flow algorithm and *MAX_FLOW* is the name of the instantiated version.

In order to use the templated version a file <LEDA/graph/templates/XXX.h> must be included, e.g., in order to use the templated version of the maxflow algorithm, one must include <LEDA/graph/templates/max_flow.h>

Special care should be taken when using network algorithms with a number type *NT* that can incur rounding error, e.g., the type *double*. The functions perform correctly if the arithmetic is exact. This is the case if all numerical values in the input are integers (albeit stored as a number of type *NT*), if none of the intermediate results exceeds the maximal integer representable by the number type (2^{52} in the case of *doubles*), and if no round-off errors occur during the computation. We give more specific information on the

arithmetic demand for each function below. If the arithmetic incurs rounding error, the computation may fail in two ways: give a wrong answer or run forever.

13.1 Basic Graph Algorithms (`basic_graph_alg`)

bool TOPSORT(*const graph& G, node_array<int>& ord*)

TOPSORT takes as argument a directed graph $G(V, E)$. It sorts G topologically (if G is acyclic) by computing for every node $v \in V$ an integer $ord[v]$ such that $1 \leq ord[v] \leq |V|$ and $ord[v] < ord[w]$ for all edges $(v, w) \in E$. TOPSORT returns true if G is acyclic and false otherwise. The algorithm ([50]) has running time $O(|V| + |E|)$.

bool TOPSORT(*const graph& G, list<node>& L*)

a variant of TOPSORT that computes a list L of nodes in topological order (if G is acyclic). It returns true if G is acyclic and false otherwise.

bool TOPSORT1(*graph& G*)

a variant of TOPSORT that rearranges nodes and edges of G in topological order (edges are sorted by the topological number of their target nodes).

list<node> DFS(*const graph& G, node s, node_array<bool>& reached*)

DFS takes as argument a directed graph $G(V, E)$, a node s of G and a *node_array* *reached* of boolean values. It performs a depth first search starting at s visiting all reachable nodes v with $reached[v] = \text{false}$. For every visited node v $reached[v]$ is changed to true. DFS returns the list of all reached nodes. The algorithm ([85]) has running time $O(|V| + |E|)$.

list<edge> DFS_NUM(*const graph& G, node_array<int>& dfsnum,*
node_array<int>& compnum)

DFS_NUM takes as argument a directed graph $G(V, E)$. It performs a depth first search of G numbering the nodes of G in two different ways. *dfsnum* is a numbering with respect to the calling time and *compnum* a numbering with respect to the completion time of the recursive calls. DFS_NUM returns a depth first search forest of G (list of tree edges). The algorithm ([85]) has running time $O(|V| + |E|)$.

list<node> BFS(*const graph& G, node s, node_array<int>& dist*)

BFS takes as argument a directed graph $G(V, E)$, a node s of G and a node array $dist$ of integers. It performs a breadth first search starting at s visiting all nodes v with $dist[v] = -1$ reachable from s . The $dist$ value of every visited node is replaced by its distance to s . BFS returns the list of all visited nodes. The algorithm ([58]) has running time $O(|V| + |E|)$.

list<node> BFS(*const graph& G, node s, node_array<int>& dist,*
node_array<edge>& pred)

performs a bread first search as described above and computes for every node v the predecessor edge $pred[v]$ in the bfs shortest path tree. (You can use the function COMPUTE_SHORTEST_PATH to extract paths from the tree (cf. Section 13.2).)

int COMPONENTS(*const graph& G, node_array<int>& compnum*)

COMPONENTS takes a graph $G(V, E)$ as argument and computes the connected components of the underlying undirected graph, i.e., for every node $v \in V$ an integer $compnum[v]$ from $[0 \dots c-1]$ where c is the number of connected components of G and v belongs to the i -th connected component iff $compnum[v] = i$. COMPONENTS returns c . The algorithm ([58]) has running time $O(|V| + |E|)$.

int STRONG_COMPONENTS(*const graph& G, node_array<int>& compnum*)

STRONG_COMPONENTS takes a directed graph $G(V, E)$ as argument and computes for every node $v \in V$ an integer $compnum[v]$ from $[0 \dots c-1]$ where c is the number of strongly connected components of G and v belongs to the i -th strongly connected component iff $compnum[v] = i$. STRONG_COMPONENTS returns c . The algorithm ([58]) has running time $O(|V| + |E|)$.

int BICONNECTED_COMPONENTS(*const graph& G*,
edge_array<int>& compnum)

BICONNECTED_COMPONENTS computes the biconnected components of the undirected version of G . A biconnected component of an undirected graph is a maximal biconnected subgraph and a biconnected graph is a graph which cannot be disconnected by removing one of its nodes. A graph having only one node is biconnected.

Let c be the number of biconnected component and let c' be the number of biconnected components containing at least one edge, $c - c'$ is the number of isolated nodes in G , where a node v is isolated if is not connected to a node different from v (it may be incident to self-loops). The function returns c and labels each edge of G (which is not a self-loop) by an integer in $[0 \dots c' - 1]$. Two edges receive the same label iff they belong to the same biconnected component. The edge labels are returned in *compnum*. Be aware that self-loops receive no label since self-loops are ignored when interpreting a graph as an undirected graph.

The algorithm ([21]) has running time $O(|V| + |E|)$.

GRAPH<node, edge> TRANSITIVE_CLOSURE(*const graph& G*)

TRANSITIVE_CLOSURE takes a directed graph $G = (V, E)$ as argument and computes the transitive closure of G . It returns a directed graph $G' = (V', E')$ such that $G'.inf(.)$ is a bijective mapping from V' to V and $(v, w) \in E' \Leftrightarrow$ there is a path from $G'.inf(v')$ to $G'.inf(w')$ in G . (The edge information of G' is undefined.) The algorithm ([40]) has running time $O(|V| \cdot |E|)$.

GRAPH<node, edge> TRANSITIVE_REDUCTION(*const graph& G*)

TRANSITIVE_REDUCTION takes a directed graph $G = (V, E)$ as argument and computes the transitive reduction of G . It returns a directed graph $G' = (V', E')$. The function $G'.inf(.)$ is a bijective mapping from V' to V . The graph G and G' have the same reachability relation, i.e. there is a path from v' to w' in $G' \Leftrightarrow$ there is a path from $G'.inf(v')$ to $G'.inf(w')$ in G . And there is no graph with the previous property and less edges than G' . (The edge information of G' is undefined.) The algorithm ([40]) has running time $O(|V| \cdot |E|)$.

void MAKE_TRANSITIVELY_CLOSED(*graph& G*)

MAKE_TRANSITIVELY_CLOSED transforms G into its transitive closure by adding edges.

void MAKE_TRANSITIVELY_REDUCED(*graph& G*)

MAKE_TRANSITIVELY_REDUCED transforms G into its transitive reduction by removing edges.

13.2 Shortest Path Algorithms (shortest_path)

Let G be a graph, s a node in G , and c a cost function on the edges of G . Edge costs may be positive or negative. For a node v let $\mu(v)$ be the length of a shortest path from s to v (more precisely, the infimum of the lengths of all paths from s to v). If v is not reachable from s then $\mu(v) = +\infty$ and if v is reachable from s through a cycle of negative cost then $\mu(v) = -\infty$. Let V^+ , V^f , and V^- be the set of nodes v with $\mu(v) = +\infty$, $-\infty < \mu(v) < +\infty$, and $\mu(v) = -\infty$, respectively.

The solution to a single source shortest path problem (G, s, c) is a pair $(dist, pred)$ where $dist$ is a *node_array*< NT > and $pred$ is a *node_array*<*edge*> with the following properties. Let $P = \{pred[v] ; v \in V \text{ and } pred[v] \neq nil\}$. A P -cycle is a cycle all of whose edges belong to P and a P -path is a path all of whose edges belong to P .

- $v \in V^+$ iff $v \neq s$ and $pred[v] = nil$ and $v \in V^f \cup V^-$ iff $v = s$ or $pred[v] \neq nil$.
- $s \in V^f$ if $pred[s] = nil$ and $s \in V^-$ otherwise.
- $v \in V^f$ if v is reachable from s by a P -path and $s \in V^f$. P restricted to V^f forms a shortest path tree and $dist[v] = \mu(s, v)$ for $v \in V^f$.
- All P -cycles have negative cost and $v \in V^-$ iff v lies on a P -cycle or is reachable from a P -cycle by a P -path.

Most functions in this section are template functions. The template parameter NT can be instantiated with any number type. In order to use the template version of the function the .h-file

```
#include <LEDA/graph/templates/shortest_path.h>
```

must be included. The functions are pre-instantiated with *int* and *double*. The function names of the pre-instantiated versions are without the suffix `_T`.

Special care should be taken when using the functions with a number type NT that can incur rounding error, e.g., the type *double*. The functions perform correctly if all arithmetic performed is without rounding error. This is the case if all numerical values in the input are integers (albeit stored as a number of type NT) and if none of the intermediate results exceeds the maximal integer representable by the number type (2^{52} in the case of *doubles*). All intermediate results are sums and differences of input values, in particular, the algorithms do not use divisions and multiplications. All intermediate values are bounded by nC where n is the number of nodes and C is the maximal absolute value of any edge cost.

```
template <class NT>
```

```
bool SHORTEST_PATH_T(const graph& G, node s, const edge_array<NT>& c,
                    node_array<NT>& dist, node_array<edge>& pred)
```

SHORTEST_PATH solves the single source shortest path problem in the graph $G(V, E)$ with respect to the source node s and the cost-function given by the `edge_array`.

The procedure returns false if there is a negative cycle in G that is reachable from s and returns true otherwise.

It runs in linear time on acyclic graph, in time $O(m + n \log n)$ if all edge costs are non-negative, and runs in time $O(\min(D, n)m)$ otherwise. Here D is the maximal number of edges on any shortest path.

```
list<edge> COMPUTE_SHORTEST_PATH(const graph& G, node s, node t,
                                const node_array<edge>& pred)
```

computes a shortest path from s to t assuming that `pred` stores a valid shortest path tree with root s (as it can be computed with the previous function). The returned list contains the edges on a shortest path from s to t . The running time is linear in the length of the path.

```
template <class NT>
```

```
node_array<int> CHECK_SP_T(const graph& G, node s, const edge_array<NT>& c,
                        const node_array<NT>& dist,
                        const node_array<edge>& pred)
```

checks whether the pair $(dist, pred)$ is a correct solution to the shortest path problem (G, s, c) and returns a `node_array<int>` `label` with `label[v] < 0` if v has distance $-\infty$ (-2 for nodes lying on a negative cycle and -1 for a node reachable from a negative cycle), `label[v] = 0` if v has finite distance, and `label[v] > 0` if v has distance $+\infty$. The program aborts if the check fails. The algorithm takes linear time.

```
template <class NT>
```

```
void ACYCLIC_SHORTEST_PATH_T(const graph& G, node s,
                             const edge_array<NT>& c,
                             node_array<NT>& dist, node_array<edge>& pred)
```

solves the single source shortest path problem with respect to source s . The algorithm takes linear time.

Precondition: G must be acyclic.

```
template <class NT>
```

```
void DIJKSTRA_T(const graph& G, node s, const edge_array<NT>& cost,
               node_array<NT>& dist, node_array<edge>& pred)
```

solves the shortest path problem in a graph with non-negative edges weights.

Precondition: The costs of all edges are non-negative.

```
template <class NT>
void DIJKSTRA_T(const graph& G, node s, const edge_array<NT>& cost,
               node_array<NT>& dist)
    as above, but pred is not computed.
```

```
template <class NT>
NT DIJKSTRA_T(const graph& G, node s, node t, const edge_array<NT>& c,
              node_array<edge>& pred)
    computes a shortest path from s to t and returns its length.
    The cost of all edges must be non-negative. The return value
    is unspecified if there is no path from s to t. The array pred
    records a shortest path from s to t in reverse order, i.e., pred[t]
    is the last edge on the path. If there is no path from s to t
    or if s = t then pred[t] = nil. The worst case running time is
     $O(m + n \log n)$ , but frequently much better.
```

```
template <class NT>
bool BELLMAN_FORD_B_T(const graph& G, node s, const edge_array<NT>& c,
                     node_array<NT>& dist, node_array<edge>& pred)
    BELLMAN_FORD_B solves the single source shortest path
    problem in the graph  $G(V, E)$  with respect to the source node
    s and the cost-function given by the edge_array c.
    BELLMAN_FORD_B returns false if there is a negative cycle
    in G that is reachable from s and returns true otherwise. The
    algorithm ([10]) has running time  $O(\min(D, n)m)$  where D
    is the maximal number of edges on any shortest path. The
    algorithm is only included for pedagogical purposes.
```

```
void BF_GEN(GRAPH<int, int>& G, int n, int m, bool non_negative = true)
    generates a graph with at most n nodes and at most m edges.
    The edge costs are stored as edge data. The running time
    of BELLMAN_FORD_B on this graph is  $\Omega(nm)$ . The edge
    weights are non-negative if non_negative is true and are arbitrary
    otherwise.
    Precondition:  $m \geq 2n$  and  $m \leq n^2/2$ .
```

```
template <class NT>
bool BELLMAN_FORD_T(const graph& G, node s, const edge_array<NT>& c,
                   node_array<NT>& dist, node_array<edge>& pred)
    BELLMAN_FORD_T solves the single source shortest path
    problem in the graph  $G(V, E)$  with respect to the source node
    s and the cost-function given by the edge_array c.
    BELLMAN_FORD_T returns false if there is a negative cycle
    in G that is reachable from s and returns true otherwise. The
    algorithm ([10]) has running time  $O(\min(D, n)m)$  where D
    is the maximal number of edges in any shortest path.
    The algorithm is never significantly slower than BELLMAN_FORD_B
    and frequently much faster.
```

template <class NT>

bool ALLPAIRS_SHORTEST_PATHS_T(graph& G, const edge_array<NT>& c,
node_matrix<NT>& DIST)

returns *true* if G has no negative cycle and returns *false* otherwise. In the latter case all values returned in $DIST$ are unspecified. In the former case the following holds for all v and w : if $\mu(v, w) < \infty$ then $DIST(v, w) = \mu(v, w)$ and if $\mu(v, w) = \infty$ then the value of $DIST(v, w)$ is arbitrary. The procedure runs in time $O(nm + n^2 \log n)$.

bool K_SHORTEST_PATHS(graph& G, node s, node t, const edge_array<int>& c, int k,
list<list<edge>*>& sps, int& nops)

$K_SHORTEST_PATHS$ solves the k shortest simple paths problem in the graph $G(V, E)$ with respect to the source node s , the target node t , and the cost-function given by the edge_array c . k is an input parameter specifying the number of paths to be computed.

sps reports the $nops$ shortest simple paths computed, each specified as a list of edges from s to t . $nops$ is an output parameter that gives the number of reported paths. It is usually k , except in the case that there are more than k shortest paths of the same length, then all of them are reported or in the case that there are less than k paths from s to t . In both cases, $nops$ deviates from k and specifies the number of reported paths.

rational MINIMUM_RATIO_CYCLE(graph& G, const edge_array<int>& c,
const edge_array<int>& p, list<edge>& C_start)

Returns a minimum cost to profit ratio cycle C_start and the ratio of the cycle. For a cycle C let $c(C)$ be the sum of the c -values of the edges on the cycle and let $p(C)$ be the sum of the p -values of the edges on the cycle. The cost to profit ratio of the cycle is the quotient $c(C)/p(C)$. The cycle C_start realizes the minimum ratio for any cycle C . The procedure runs in time $O(nm \log(n \cdot C \cdot P))$ where C and P are the maximum cost and profit of any edge, respectively. The function returns zero if there is no cycle in G .

Precondition: There are no cycles of cost zero or less with respect to either c or p .

13.3 Maximum Flow (max_flow)

Let $G = (V, E)$ be a directed graph, let s and t be distinct vertices in G and let $cap : E \rightarrow \mathbb{R}_{\geq 0}$ be a non-negative function on the edges of G . For an edge e , we call $cap(e)$ the *capacity* of e . An (s, t) -*flow* or simply *flow* is a function $f : E \rightarrow \mathbb{R}_{\geq 0}$ satisfying the capacity constraints and the flow conservation constraints:

$$(1) \quad 0 \leq f(e) \leq cap(e) \quad \text{for every edge } e \in E$$

$$(2) \quad \sum_{e; source(e)=v} f(e) = \sum_{e; target(e)=v} f(e) \quad \text{for every node } v \in V \setminus \{s, t\}$$

The value of the flow is the net flow into t (equivalently, the net flow out of s). The net flow into t is the flow into t minus the flow out of t . A flow is maximum if its value is at least as large as the value of any other flow.

All max flow implementations are template functions. The template parameter NT can be instantiated with any number type. In order to use the template version of the function the files

```
#include <LEDA/graph/graph_alg.h>
#include <LEDA/graph/templates/max_flow.h>
```

must be included.

There are pre-instantiations for the number types *int* and *double*. The pre-instantiated versions have the same function names except for the suffix `_T`. In order to use them either

```
#include <LEDA/graph/max_flow.h>
```

or

```
#include <LEDA/graph/graph_alg.h>
```

has to be included (the latter file includes the former). The connection between template functions and pre-instantiated functions is discussed in detail in the section “Templates for Network Algorithms” of the LEDA book.

Special care should be taken when using the template functions with a number type NT that can incur rounding error, e.g., the type *double*. The section “Algorithms on Weighted Graphs and Arithmetic Demand” of the LEDA book contains a general discussion of this issue. The template functions are only guaranteed to perform correctly if all arithmetic performed is without rounding error. This is the case if all numerical values in the input are integers (albeit stored as a number of type NT) and if none of the intermediate results exceeds the maximal integer representable by the number type ($2^{53} - 1$ in the case of *doubles*). All intermediate results are sums and differences of input values, in particular, the algorithms do not use divisions and multiplications.

The algorithms have the following arithmetic demands. Let C be the maximal absolute value of any edge capacity. If all capacities are integral then all intermediate values are bounded by $d \cdot C$, where d is the out-degree of the source.

The pre-instantiations for number type *double* compute the maximum flow for a modified capacity function *cap1*, where for every edge e

$$cap1[e] = sign(cap[e]) \lfloor |cap[e]| \cdot S \rfloor / S$$

and S is the largest power of two such that $S < 2^{53}/(d \cdot C)$.

The value of the maximum flow for the modified capacity function and the value of the maximum flow for the original capacity function differ by at most $m \cdot d \cdot C \cdot 2^{-52}$.

The following functions are available:

```
template <class NT>
```

```
__INLINE NT MAX_FLOW_T(const graph& G, node s, node t,
                      const edge_array<NT>& cap, edge_array<NT>& f)
```

computes a maximum (s, t) -flow f in the network (G, s, t, cap) and returns the value of the flow.

The implementation uses the preflow-push method of Goldberg and Tarjan [43] with the local and global relabeling heuristic and the gap heuristic. The highest level rule is used to select active nodes. The section on maximum flow of the LEDA book gives full information.

```
template <class NT>
```

```
__INLINE NT MAX_FLOW_T(const graph& G, node s, node t,
                      const edge_array<NT>& cap, edge_array<NT>& f,
                      list<node>& st_cut)
```

as above, also computes a minimum $s - t$ cut in G .

```
template <class NT>
```

```
__INLINE bool CHECK_MAX_FLOW_T(const graph& G, node s, node t,
                              const edge_array<NT>& cap,
                              const edge_array<NT>& f)
```

checks whether f is a maximum flow in the network (G, s, t, cap) . The function returns false if this is not the case.

```
bool MAX_FLOW_SCALE_CAPS(const graph& G, node s, edge_array<double>& cap)
```

replaces $cap[e]$ by $cap1[e]$ for every edge e , where $cap1[e]$ is as defined above. The function returns *false* if the scaling changed some capacity, and returns *true* otherwise.

```
template <class NT>
```

```
__INLINE NT MAX_FLOW_T(graph& G, node s, node t, const edge_array<NT>& lcap,
                      const edge_array<NT>& ucap, edge_array<NT>& f)
```

computes a maximum (s, t) -flow f in the network $(G, s, t, ucap)$ s.th. $f(e) \leq lcap[e]$ for every edge e . If a feasible flow exists, its value returned; otherwise the return value is -1.

void max_flow_gen_rand(*GRAPH*<*int*, *int*>& *G*, *node*& *s*, *node*& *t*, *int* *n*, *int* *m*)

A random graph with *n* nodes, *m* edges, and random edge capacities in [2,11] for the edges out of *s* and in [1,10] for all other edges.

void max_flow_gen_CG1(*GRAPH*<*int*, *int*>& *G*, *node*& *s*, *node*& *t*, *int* *n*)

A generator suggested by Cherkassky and Goldberg.

void max_flow_gen_CG2(*GRAPH*<*int*, *int*>& *G*, *node*& *s*, *node*& *t*, *int* *n*)

Another generator suggested by Cherkassky and Goldberg.

void max_flow_gen_AMO(*GRAPH*<*int*, *int*>& *G*, *node*& *s*, *node*& *t*, *int* *n*)

A generator suggested by Ahuja, Magnanti, and Orlin.

13.4 Min Cost Flow Algorithms (min_cost_flow)

bool FEASIBLE_FLOW(*const graph*& *G*, *const node_array*<*int*>& *supply*,
const edge_array<*int*>& *lcap*,
const edge_array<*int*>& *ucap*, *edge_array*<*int*>& *flow*)

FEASIBLE_FLOW takes as arguments a directed graph *G*, two edge_arrays *lcap* and *ucap* giving for each edge a lower and upper capacity bound, an edge_array *cost* specifying for each edge an integer cost and a node_array *supply* defining for each node *v* a supply or demand (if *supply*[*v*] < 0). If a feasible flow (fulfilling the capacity and mass balance conditions) exists it computes such a *flow* and returns *true*, otherwise *false* is returned.

bool FEASIBLE_FLOW(*const graph*& *G*, *const node_array*<*int*>& *supply*,
const edge_array<*int*>& *cap*, *edge_array*<*int*>& *flow*)
as above, but assumes that *lcap*[*e*] = 0 for every edge *e* ∈ *E*.

bool `MIN_COST_FLOW(const graph& G, const edge_array<int>& lcap,`
 `const edge_array<int>& ucap,`
 `const edge_array<int>& cost,`
 `const node_array<int>& supply,`
 `edge_array<int>& flow)`

`MIN_COST_FLOW` takes as arguments a directed graph $G(V, E)$, an edge_array *lcap* (*ucap*) giving for each edge a lower (upper) capacity bound, an edge_array *cost* specifying for each edge an integer cost and a node_array *supply* defining for each node v a supply or demand (if $supply[v] < 0$). If a feasible flow (fulfilling the capacity and mass balance conditions) exists it computes such a *flow* of minimal cost and returns *true*, otherwise *false* is returned.

bool `MIN_COST_FLOW(const graph& G, const edge_array<int>& cap,`
 `const edge_array<int>& cost,`
 `const node_array<int>& supply,`
 `edge_array<int>& flow)`

This variant of `MIN_COST_FLOW` assumes that $lcap[e] = 0$ for every edge $e \in E$.

int `MIN_COST_MAX_FLOW(const graph& G, node s, node t,`
 `const edge_array<int>& cap,`
 `const edge_array<int>& cost,`
 `edge_array<int>& flow)`

`MIN_COST_MAX_FLOW` takes as arguments a directed graph $G(V, E)$, a source node s , a sink node t , an edge_array *cap* giving for each edge in G a capacity, and an edge_array *cost* specifying for each edge an integer cost. It computes for every edge e in G a flow $flow[e]$ such that the total flow from s to t is maximal, the total cost of the flow is minimal, and $0 \leq flow[e] \leq cap[e]$ for all edges e . `MIN_COST_MAX_FLOW` returns the total flow from s to t .

13.5 Minimum Cut (`min_cut`)

A cut C in a network is a set of nodes that is neither empty nor the entire set of nodes. The weight of a cut is the sum of the weights of the edges having exactly one endpoint in C .

int MIN_CUT(*const graph& G, const edge_array<int>& weight,*
 list<node>& C, bool use_heuristic = true)

MIN_CUT takes a graph G and an edge_array $weight$ that gives for each edge a *non-negative* integer weight. The algorithm ([82]) computes a cut of minimum weight. A cut of minimum weight is returned in C and the value of the cut is the return value of the function. The running time is $O(nm + n^2 \log n)$. The function uses a heuristic to speed up its computation.
Precondition: The edge weights are non-negative.

list<node> MIN_CUT(*const graph& G, const edge_array<int>& weight*)
 as above, but the cut C is returned.

int CUT_VALUE(*const graph& G, const edge_array<int>& weight,*
 const list<node>& C)
 returns the value of the cut C .

13.6 Maximum Cardinality Matchings in Bipartite Graphs (`mcb_matching`)

A *matching* in a graph G is a subset M of the edges of G such that no two share an endpoint. A *node cover* is a set of nodes NC such that every edge has at least one endpoint in NC . The maximum cardinality of a matching is at most the minimum cardinality of a node cover. In bipartite graph, the two quantities are equal.

`list<edge> MAX_CARD_BIPARTITE_MATCHING(graph& G)`

returns a maximum cardinality matching.

Precondition: G must be bipartite.

`list<edge> MAX_CARD_BIPARTITE_MATCHING(graph& G, node_array<bool>& NC)`

returns a maximum cardinality matching and a minimum cardinality node cover NC . The node cover has the same cardinality as the matching and hence proves the optimality of the matching. *Precondition:* G must be bipartite.

`bool CHECK_MCB(const graph& G, const list<edge>& M,
const node_array<bool>& NC)`

checks that M is a matching in G , i.e., that at most one edge in M is incident to any node of G , that NC is a node cover, i.e., for every edge of G at least one endpoint is in NC and that M and NC have the same cardinality. The function writes diagnostic output to `cerr`, if one of the conditions is violated.

`list<edge> MAX_CARD_BIPARTITE_MATCHING(graph& G, const list<node>& A,
const list<node>& B)`

returns a maximum cardinality matching. *Precondition:* G must be bipartite. The bipartition of G is given by A and B . All edges of G must be directed from A to B .

`list<edge> MAX_CARD_BIPARTITE_MATCHING(graph& G, const list<node>& A,
const list<node>& B,
node_array<bool>& NC)`

returns a maximum cardinality matching. A minimal node cover is returned in NC . The node cover has the same cardinality as the matching and hence proves the maximality of the matching. *Precondition:* G must be bipartite. The bipartition of G is given by A and B . All edges of G must be directed from A to B .

We offer several implementations of bipartite matching algorithms. All of them require

that the bipartition (A, B) is given and that all edges are directed from A to B ; all of them return a maximum cardinality matching and a minimum cardinality node cover. The initial characters of the inventors are used to distinguish between the algorithms. The common interface is

```
list<edge> MAX_CARD_BIPARTITE_MATCHING_XX(graph& G,
                                         const list<node>& A,
                                         const list<node>& B,
                                         node_array<bool>& NC,
                                         bool use_heuristic = true);
```

where *XX* is to be replaced by either *HK*, *ABMP*, *FF*, or *FFB*. All algorithms can be asked to use a heuristic to find an initial matching. This is the default.

HK stands for the algorithm due to Hopcroft and Karp [44]. It has running time $O(\sqrt{nm})$.

ABMP stands for algorithm due to Alt, Blum, Mehlhorn, and Paul [1]. The algorithm has running time $O(\sqrt{nm})$. The algorithm consists of two major phases. In the first phase all augmenting paths of length less than $Lmax$ are found, and in the second phase the remaining augmenting paths are determined. The default value of $Lmax$ is $0.1\sqrt{n}$. $Lmax$ is an additional optional parameter of the procedure.

FF stands for the algorithm due to Ford and Fulkerson [34]. The algorithm has running time $O(nm)$ and *FFB* stands for a simple and slow version of *FF*. The algorithm *FF* has an additional optional parameter *use_bfs* of type *bool*. If set to true, breadth-first-search is used in the search for augmenting paths, and if set to false, depth-first-search is used.

Be aware that the algorithms *_XX* change the graph G . They leave the graph structure unchanged but reorder adjacency lists (and hence change the embedding). If this is undesirable you must restore the original order of the adjacency lists as follows.

```
edge_array<int> edge_number(G); int i = 0;
forall_nodes(v,G)
    forall_adj_edges(e,G) edge_number[e] = i++;
call matching algorithm;
G.sort_edges(edge_number);
```

13.7 Bipartite Weighted Matchings and Assignments (*mwb_matching*)

We give functions

- to compute maximum and minimum weighted matchings in bipartite graph,
- to check the optimality of matchings, and
- to scale edge weights, so as to avoid round-off errors in computations with the number type *double*.

All functions for computing maximum or minimum weighted matchings provide a proof of optimality in the form of a potential function *pot*; see the chapter on bipartite weighted matchings of the LEDA book for a discussion of potential functions.

The functions in this section are template functions. The template parameter *NT* can be instantiated with any number type. In order to use the template version of the function the appropriate .h-file must be included.

```
#include <LEDA/graph/templates/mwb_matching.h>
```

There are pre-instantiations for the number types *int* and *double*. The pre-instantiated versions have the same function names except for the suffix *_T*. In order to use them either

```
#include <LEDA/graph/mwb_matching.h>
```

or

```
#include <LEDA/graph/graph_alg.h>
```

has to be included (the latter file includes the former). The connection between template functions and pre-instantiated functions is discussed in detail in the section “Templates for Network Algorithms” of the LEDA book. The function names of the pre-instantiated versions and the template versions only differ by an additional suffix *_T* in the names of the latter ones.

Special care should be taken when using the template functions with a number type *NT* that can incur rounding error, e.g., the type *double*. The section “Algorithms on Weighted Graphs and Arithmetic Demand” of the LEDA book contains a general discussion of this issue. The template functions are only guaranteed to perform correctly if all arithmetic performed is without rounding error. This is the case if all numerical values in the input are integers (albeit stored as a number of type *NT*) and if none of the intermediate results exceeds the maximal integer representable by the number type ($2^{53} - 1$ in the case of *doubles*). All intermediate results are sums and differences of input values, in particular, the algorithms do not use divisions and multiplications.

The algorithms have the following arithmetic demands. Let *C* be the maximal absolute value of any edge cost. If all weights are integral then all intermediate values are bounded by $3C$ in the case of maximum weight matchings and by $4nC$ in the case of the other matching algorithms. Let $f = 3$ in the former case and let $f = 4n$ in the latter case.

The pre-instantiations for number type *double* compute the optimal matching for a modified weight function $c1$, where for every edge e

$$c1[e] = \text{sign}(c[e]) \lfloor |c[e]| \cdot S \rfloor / S$$

and S is the largest power of two such that $S < 2^{53}/(f \cdot C)$.

The weight of the optimal matching for the modified weight function and the weight of the optimal matching for the original weight function differ by at most $n \cdot f \cdot C \cdot 2^{-52}$.

template <class NT>

```
list<edge> MAX_WEIGHT_BIPARTITE_MATCHING_T(graph& G,
                                           const edge_array<NT>& c,
                                           node_array<NT>& pot)
```

computes a matching of maximal cost and a potential function pot that is tight with respect to M . The running time of the algorithm is $O(n \cdot (m + n \log n))$. The argument pot is optional.

Precondition: G must be bipartite.

template <class NT>

```
list<edge> MAX_WEIGHT_BIPARTITE_MATCHING_T(graph& G,
                                           const list<node>& A,
                                           const list<node>& B,
                                           const edge_array<NT>& c,
                                           node_array<NT>& pot)
```

As above. It is assumed that the partition (A, B) witnesses that G is bipartite and that all edges of G are directed from A to B . If A and B have different sizes then it is advisable that A is the smaller set; in general, this leads to smaller running time. The argument pot is optional.

template <class NT>

```
bool CHECK_MWBMT(const graph& G, const edge_array<NT>& c,
                 const list<edge>& M, const node_array<NT>& pot)
```

checks that pot is a tight feasible potential function with respect to M and that M is a matching. Tightness of pot implies that M is a maximum weighted matching.

template <class NT>

```
list<edge> MAX_WEIGHT_ASSIGNMENT_T(graph& G, const edge_array<NT>& c,
                                   node_array<NT>& pot)
```

computes a perfect matching of maximal cost and a potential function pot that is tight with respect to M . The running time of the algorithm is $O(n \cdot (m + n \log n))$. If G contains no perfect matching the empty set of edges is returned. The argument pot is optional.

Precondition: G must be bipartite.

```

template <class NT>
list<edge> MAX_WEIGHT_ASSIGNMENT_T(graph& G, const list<node>& A,
                                const list<node>& B,
                                const edge_array<NT>& c,
                                node_array<NT>& pot)

```

As above. It is assumed that the partition (A, B) witnesses that G is bipartite and that all edges of G are directed from A to B . The argument pot is optional.

```

template <class NT>
bool CHECK_MAX_WEIGHT_ASSIGNMENT_T(const graph& G,
                                  const edge_array<NT>& c,
                                  const list<edge>& M,
                                  const node_array<NT>& pot)

```

checks that pot is a tight feasible potential function with respect to M and that M is a perfect matching. Tightness of pot implies that M is a maximum cost assignment.

```

template <class NT>
list<edge> MIN_WEIGHT_ASSIGNMENT_T(graph& G, const edge_array<NT>& c,
                                  node_array<NT>& pot)

```

computes a perfect matching of minimal cost and a potential function pot that is tight with respect to M . The running time of the algorithm is $O(n \cdot (m + n \log n))$. If G contains no perfect matching the empty set of edges is returned. The argument pot is optional.

Precondition: G must be bipartite.

```

template <class NT>
list<edge> MIN_WEIGHT_ASSIGNMENT_T(graph& G, const list<node>& A,
                                  const list<node>& B,
                                  const edge_array<NT>& c,
                                  node_array<NT>& pot)

```

As above. It is assumed that the partition (A, B) witnesses that G is bipartite and that all edges of G are directed from A to B . The argument pot is optional.

```
template <class NT>
```

```
bool CHECK_MIN_WEIGHT_ASSIGNMENT_T(const graph& G,
                                   const edge_array<NT>& c,
                                   const list<edge>& M,
                                   const node_array<NT>& pot)
```

checks that *pot* is a tight feasible potential function with respect to *M* and that *M* is a perfect matching. Tightness of *pot* implies that *M* is a minimum cost assignment.

```
template <class NT>
```

```
list<edge> MWMCB_MATCHING_T(graph& G, const list<node>& A,
                             const list<node>& B, const edge_array<NT>& c,
                             node_array<NT>& pot)
```

Returns a maximum weight matching among the matchings of maximum cardinality. The potential function *pot* is tight with respect to a modified cost function which increases the cost of every edge by $L = 1 + 2kC$ where C is the maximum absolute value of any weight and $k = \min(|A|, |B|)$. It is assumed that the partition (A, B) witnesses that G is bipartite and that all edges of G are directed from A to B . If A and B have different sizes, it is advisable that A is the smaller set; in general, this leads to smaller running time. The argument *pot* is optional.

```
bool MWBMSCALE_WEIGHTS(const graph& G, edge_array<double>& c)
```

replaces $c[e]$ by $c1[e]$ for every edge e , where $c1[e]$ was defined above and $f = 3$. This scaling function is appropriate for the maximum weight matching algorithm. The function returns *false* if the scaling changed some weight, and returns *true* otherwise.

```
bool MWA_SCALE_WEIGHTS(const graph& G, edge_array<double>& c)
```

replaces $c[e]$ by $c1[e]$ for every edge e , where $c1[e]$ was defined above and $f = 4n$. This scaling function should be used for the algorithms that compute minimum of maximum weight assignments or maximum weighted matchings of maximum cardinality. The function returns *false* if the scaling changed some weight, and returns *true* otherwise.

13.8 Maximum Cardinality Matchings in General Graphs (mc_matching)

A *matching* in a graph G is a subset M of the edges of G such that no two share an endpoint.

An odd-set cover *OSC* of G is a labeling of the nodes of G with non-negative integers such that every edge of G (which is not a self-loop) is either incident to a node labeled 1

or connects two nodes labeled with the same i , $i \geq 2$.

Let n_i be the number of nodes labeled i and consider any matching N . For i , $i \geq 2$, let N_i be the edges in N that connect two nodes labeled i . Let N_1 be the remaining edges in N . Then $|N_i| \leq \lfloor n_i/2 \rfloor$ and $|N_1| \leq n_1$ and hence

$$|N| \leq n_1 + \sum_{i \geq 2} \lfloor n_i/2 \rfloor$$

for any matching N and any odd-set cover OSC .

It can be shown that for a maximum cardinality matching M there is always an odd-set cover OSC with

$$|M| = n_1 + \sum_{i \geq 2} \lfloor n_i/2 \rfloor,$$

thus proving the optimality of M . In such a cover all n_i with $i \geq 2$ are odd, hence the name.

list<edge> MAX_CARD_MATCHING(*const graph& G*, *node_array<int>& OSC*,
int heur = 0)

computes a maximum cardinality matching M in G and returns it as a list of edges. The algorithm ([26], [38]) has running time $O(nm \cdot \alpha(n, m))$. With $heur = 1$ the algorithm uses a greedy heuristic to find an initial matching. This seems to have little effect on the running time of the algorithm.

An odd-set cover that proves the maximality of M is returned in OSC .

list<edge> MAX_CARD_MATCHING(*const graph& G*, *int heur = 0*)

as above, but no proof of optimality is returned.

bool CHECK_MAX_CARD_MATCHING(*const graph& G*, *const list<edge>& M*,
const node_array<int>& OSC)

checks whether M is a maximum cardinality matching in G and OSC is a proof of optimality. Aborts if this is not the case.

13.9 General Weighted Matchings (`mw_matching`)

We give functions

- to compute maximum-weight matchings,
- to compute maximum-weight or minimum-weight perfect matchings, and
- to check the optimality of weighted matchings

in general graph.

You may skip the following subsections and restrict on reading the function signatures and the corresponding comments in order to use these functions. If you are interested in technical details, or if you would like to ensure that the input data is well chosen, or if you would like to know the exact meaning of all output parameters, you should continue reading.

The functions in this section are template functions. It is intended that in the near future the template parameter NT can be instantiated with any number type. **Please note that for the time being the template functions are only guaranteed to perform correctly for the number type `int`.** In order to use the template version of the function the appropriate .h-file must be included.

```
#include <LEDA/graph/templates/mw_matching.h>
```

There are pre-instantiations for the number types *int*. In order to use them either

```
#include <LEDA/graph/mw_matching.h>
```

or

```
#include <LEDA/graph/graph_alg.h>
```

has to be included (the latter file includes the former). The connection between template functions and pre-instantiated functions is discussed in detail in the section “Templates for Network Algorithms” of the LEDA book. The function names of the pre-instantiated versions and the template versions only differ by an additional suffix `_T` in the names of the latter ones.

Proof of Optimality. Most of the functions for computing maximum or minimum weighted matchings provide a proof of optimality in the form of a dual solution represented by pot , BT and b . We briefly discuss their semantics: Each node is associated with a potential which is stored in the node array pot . The array BT (type $array<two_tuple<NT, int>>$) is used to represent the *nested family of odd cardinality sets* which is constructed during the course of the algorithm. For each (non-trivial) blossom B , a two tuple (z_B, p_B) is stored in BT , where z_B is the potential and p_B is the *parent index* of B . The parent index p_B is set to -1 if B is a surface blossom. Otherwise, p_B stores the index of the entry in BT corresponding to the immediate super-blossom of B . The index range of BT is $[0, \dots, k - 1]$, where k denotes the number of (non-trivial) blossoms. Let B' be a sub-blossom of B and let the corresponding index of B' and B in BT be denoted by i' and i , respectively. Then, $i' < i$. In b (type $node_array<int>$) the parent index for each node u is stored (-1 if u is not contained in any blossom).

Heuristics for Initial Matching Constructions. Each function can be asked to start with either an empty matching ($heur = 0$), a greedy matching ($heur = 1$) or an (adapted) fractional matching ($heur = 2$); by default, the fractional matching heuristic is used.

Graph Structure. All functions assume the underlying graph (type *graph*) to be connected, simple, and loopfree. They work on the underlying undirected graph of the directed graph parameter.

Edge Weight Restrictions. The algorithms use divisions. In order to avoid rounding errors for the number type *int*, **please make sure that all edge weights are multiples of 4; the algorithm will automatically multiply all edge weights by 4 if this condition is not met.** (Then, however, the returned dual solution is valid only with respect to the modified weight function.) Moreover, in the maximum-weight (non-perfect) matching case all edge weights are assumed to be non-negative.

Arithmetic Demand. The arithmetic demand for integer edge weights is as follows. Let C denote the maximal absolute value of any edge weight and let n be the number of nodes of the graph.

In the perfect weighted matching case we have for a potential $pot[u]$ of a node u and for a potential z_B of a blossom B :

$$-nC/2 \leq pot[u] \leq (n+1)C/2 \quad \text{and} \quad -nC \leq z_B \leq nC.$$

In the non-perfect matching case we have for a potential $pot[u]$ of a node u and for a potential z_B of a blossom B :

$$0 \leq pot[u] \leq C \quad \text{and} \quad 0 \leq z_B \leq C.$$

The function *CHECK_WEIGHTS* may be used to test whether the edge weights are feasible or not. It is automatically called at the beginning of each of the algorithms provided in this chapter.

Single Tree vs. Multiple Tree Approach: All functions can either run a *single tree approach* or a *multiple tree approach*. In the single tree approach, one alternating tree is grown from a free node at a time. In the multiple tree approach, multiple alternating trees are grown simultaneously from all free nodes. On large instances, the multiple tree approach is significantly faster and therefore is used by default. If `#define _SST_APPROACH` is defined *before* the template file is included all functions will run the single tree approach.

Worst-Case Running Time: All functions for computing maximum or minimum weighted (perfect or non-perfect) matchings guarantee a running time of $O(nm \log n)$, where n and m denote the number of nodes and edges, respectively.

```
template <class NT>
```

```
list<edge> MAX_WEIGHT_MATCHING_T(const graph& G, const edge_array<NT>& w,
                                bool check = true, int heur = 2)
```

computes a maximum-weight matching M of the underlying undirected graph of graph G with weight function w . If *check* is set to *true*, the optimality of M is checked internally. The heuristic used for the construction of an initial matching is determined by *heur*.

Precondition: All edge weights must be non-negative.

```
template <class NT>
```

```
list<edge> MAX_WEIGHT_MATCHING_T(const graph& G, const edge_array<NT>& w,
                                node_array<NT>& pot, array<two_tuple<NT,
                                int>>& BT, node_array<int>& b,
                                bool check = true, int heur = 2)
```

computes a maximum-weight matching M of the underlying undirected graph of graph G with weight function w . The function provides a proof of optimality in the form of a dual solution given by *pot*, *BT* and *b*. If *check* is set to *true*, the optimality of M is checked internally. The heuristic used for the construction of an initial matching is determined by *heur*.

Precondition: All edge weights must be non-negative.

```
template <class NT>
```

```
bool CHECK_MAX_WEIGHT_MATCHING_T(const graph& G,
                                  const edge_array<NT>& w,
                                  const list<edge>& M,
                                  const node_array<NT>& pot,
                                  const array<two_tuple<NT, int>
                                  >& BT, const node_array<int>& b)
```

checks if M together with the dual solution represented by *pot*, *BT* and *b* are optimal. The function returns *true* if M is a maximum-weight matching of G with weight function w .

```
template <class NT>
```

```
list<edge> MAX_WEIGHT_PERFECT_MATCHING_T(const graph& G,
                                         const edge_array<NT>& w,
                                         bool check = true,
                                         int heur = 2)
```

computes a maximum-weight perfect matching M of the underlying undirected graph of graph G and weight function w . If G contains no perfect matching the empty set of edges is returned. If $check$ is set to *true*, the optimality of M is checked internally. The heuristic used for the construction of an initial matching is determined by *heur*.

```
template <class NT>
list<edge> MAX_WEIGHT_PERFECT_MATCHING_T(const graph& G,
                                         const edge_array<NT>& w,
                                         node_array<NT>& pot,
                                         array<two_tuple<NT, int>
                                         >& BT, node_array<int>& b,
                                         bool check = true,
                                         int heur = 2)
```

computes a maximum-weight perfect matching M of the underlying undirected graph of graph G with weight function w . If G contains no perfect matching the empty set of edges is returned. The function provides a proof of optimality in the form of a dual solution given by *pot*, *BT* and *b*. If $check$ is set to *true*, the optimality of M is checked internally. The heuristic used for the construction of an initial matching is determined by *heur*.

```
template <class NT>
bool CHECK_MAX_WEIGHT_PERFECT_MATCHING_T(const graph& G,
                                         const edge_array<NT>& w,
                                         const list<edge>& M,
                                         const node_array<NT>& pot,
                                         const array<two_tuple<NT,
                                         int> >& BT,
                                         const node_array<int>& b)
```

checks if M together with the dual solution represented by *pot*, *BT* and *b* are optimal. The function returns *true* iff M is a maximum-weight perfect matching of G with weight function w .

```
template <class NT>
```

```
list<edge> MIN_WEIGHT_PERFECT_MATCHING_T(const graph& G,
                                         const edge_array<NT>& w,
                                         bool check = true,
                                         int heur = 2)
```

computes a minimum-weight perfect matching M of the underlying undirected graph of graph G with weight function w . If G contains no perfect matching the empty set of edges is returned. If $check$ is set to *true*, the optimality of M is checked internally. The heuristic used for the construction of an initial matching is determined by *heur*.

```
template <class NT>
list<edge> MIN_WEIGHT_PERFECT_MATCHING_T(const graph& G,
                                         const edge_array<NT>& w,
                                         node_array<NT>& pot,
                                         array<two_tuple<NT, int>
                                         >& BT, node_array<int>& b,
                                         bool check = true,
                                         int heur = 2)
```

computes a minimum-weight perfect matching M of the underlying undirected graph of graph G with weight function w . If G contains no perfect matching the empty set of edges is returned. The function provides a proof of optimality in the form of a dual solution given by *pot*, *BT* and *b*. If $check$ is set to *true*, the optimality of M is checked internally. The heuristic used for the construction of an initial matching is determined by *heur*.

```
template <class NT>
bool CHECK_MIN_WEIGHT_PERFECT_MATCHING_T(const graph& G,
                                         const edge_array<NT>& w,
                                         const list<edge>& M,
                                         const node_array<NT>& pot,
                                         const array<two_tuple<NT,
                                         int> >& BT,
                                         const node_array<int>& b)
```

checks if M together with the dual solution represented by *pot*, *BT* and *b* are optimal. The function returns *true* iff M is a minimum-weight matching of G with weight function w .

```
template <class NT>
```

bool CHECK_WEIGHTS_T(*const graph& G*, *edge_array<NT>& w*, *bool perfect*)
returns *true*, if *w* is a feasible weight function for *G*; *false* otherwise. *perfect* must be set to *true* in the perfect matching case; otherwise it must be set to *false*. If the edge weights are not multiplicatives of 4 all edge weights will be scaled by a factor of 4. The modified weight function is returned in *w* then. This function is automatically called by each of the maximum weighted matching algorithms provided in this chapter, the user does not have to take care of it.

13.10 Stable Matching (stable_matching)

We are given a bipartite graph $G = (A \cup B, E)$ in which the edges incident to every vertex are linearly ordered. The order expresses preferences. A matching M in G is *stable* if there is no pair $(a, b) \in E \setminus M$ such that (1) a is unmatched or prefers b over its partner in M and (2) b is unmatched or prefers a over its partner in M . In such a situation a has the intention to switch to b and b has the intention to switch to a , i.e., the pairing is unstable.

We provide a function to compute a correct input graph from the preference data, a function that computes the stable matching when the graph is given and a function that checks whether a given matching is stable.

```
void      StableMatching(const graph& G, const list<node>& A,
                        const list<node>& B, list<edge>& M)
```

The function takes a bipartite graph G with sides A and B and computes a maximal stable matching M which is A -optimal. The graph is assumed to be bidirected, i.e, for each $(a, b) \in E$ we also have $(b, a) \in E$. It is assumed that adjacency lists record the preferences of the vertices. The running time is $O(n + m)$.
Precondition: The graph G is bidirected and a map. Sets A and B only contain nodes of graph G . In addition they are disjoint from each other.

```
bool      CheckStableMatching(const graph& G, const list<node>& A,
                              const list<node>& B, const list<edge>& M)
```

returns true if M is a stable matching in G . The running time is $O(n + m)$.
Precondition: A and B only contain nodes from G . The graph G is bipartite with respect to lists A and B .

```
void CreateInputGraph(graph& G, list<node>& A, list<node>& B,
    node_map<int>& nodes_a, node_map<int>& nodes_b,
    const list<int>& InputA, const list<int>& InputB,
    const map<int, list<int>>& preferencesA,
    const map<int, list<int>>& preferencesB)
```

The function takes a list of objects *InputA* and a list of objects *InputB*. The objects are represented by integer numbers, multiple occurrences of the same number in the same list are ignored. The maps *preferencesA* and *preferencesB* give for each object *i* the list of partner candidates with respect to a matching. The lists are decreasingly ordered according to the preferences. The function computes the input data *G*, *A* and *B* for calling the function *StableMatching(constgraph&, ...)*. The maps *nodes_a* and *nodes_b* provide the objects in *A* and *B* corresponding to the nodes in the graph.

Precondition: The entries in the lists in the preference maps only contain elements from *InputB* resp. *InputA*.

There are no multiple occurrences of an element in the same such list.

13.11 Minimum Spanning Trees (min_span)

list<edge> SPANNING_TREE(*const graph& G*)

SPANNING_TREE takes as argument a graph $G(V, E)$. It computes a spanning tree T of the underlying undirected graph, SPANNING_TREE returns the list of edges of T . The algorithm ([58]) has running time $O(|V| + |E|)$.

void SPANNING_TREE1(*graph& G*)

SPANNING_TREE takes as argument a graph $G(V, E)$. It computes a spanning tree T of the underlying undirected graph by deleting the edges in G that do not belong to T . The algorithm ([58]) has running time $O(|V| + |E|)$.

list<edge> MIN_SPANNING_TREE(*const graph& G, const edge_array<int>& cost*)

MIN_SPANNING_TREE takes as argument a graph $G(V, E)$ and an edge_array *cost* giving for each edge an integer cost. It computes a minimum spanning tree T of the underlying undirected graph of graph G , i.e., a spanning tree such that the sum of all edge costs is minimal. MIN_SPANNING_TREE returns the list of edges of T . The algorithm ([52]) has running time $O(|E| \log |V|)$.

list<edge> MIN_SPANNING_TREE(*const graph& G,*
const leda_cmp_base<edge>& cmp)

A variant using a *compare object* to compare edge costs.

list<edge> MIN_SPANNING_TREE(*const graph& G, int (*cmp)(const edge& ,*
const edge&))

A variant using a *compare function* to compare edge costs.

13.12 Euler Tours (`euler_tour`)

An Euler tour in an undirected graph G is a cycle using every edge of G exactly once. A graph has an Euler tour if it is connected and the degree of every vertex is even.

bool Euler_Tour(*const graph& G, list<two_tuple<edge, int>>& T*)

The function returns true if the underlying undirected version of graph G has an Euler tour. The Euler tour is returned in T . The items in T are of the form $(e, \pm 1)$, where the second component indicates the traversal direction d of the edge. If $d = +1$, the edge is traversed in forward direction, and if $d = -1$, the edge is traversed in reverse direction. The running time is $O(n + m)$.

bool Check_Euler_Tour(*const graph& G, const list<two_tuple<edge, int>>& T*)

returns true if T is an Euler tour in G . The running time is $O(n + m)$.

bool Euler_Tour(*graph& G, list<edge>& T*)

The function returns true if the underlying undirected version of G has an Euler tour. G is reoriented such that every node has indegree equal to its outdegree and an Euler tour (of the reoriented graph) is returned in T . The running time is $O(n + m)$.

bool Check_Euler_Tour(*const graph& G, const list<edge>& T*)

returns true if T is an Euler tour in the directed graph G . The running time is $O(n + m)$.

13.13 Algorithms for Planar Graphs (plane_graph_alg)

node ST_NUMBERING(*const graph& G, node_array<int>& stnum,*
list<node>& stlist, edge e_st = nil)

ST_NUMBERING computes an *st*-numbering of G . If e_st is nil then t is set to some arbitrary node of G . The node s is set to a neighbor of t and is returned. If e_st is not nil then s is set to the source of e_st and t is set to its target. The nodes of G are numbered such that s has number 1, t has number n , and every node v different from s and t has a smaller and a larger numbered neighbor. The ordered list of nodes is returned in *stlist*. If G has no nodes then *nil* is returned and if G has exactly one node then this node is returned and given number one.

Precondition: G is biconnected.

bool PLANAR(*graph& , bool embed = false*)

PLANAR takes as input a directed graph $G(V, E)$ and performs a planarity test for it. G must not contain self-loops. If the second argument *embed* has value *true* and G is a planar graph it is transformed into a planar map (a combinatorial embedding such that the edges in all adjacency lists are in clockwise ordering). PLANAR returns true if G is planar and false otherwise. The algorithm ([45]) has running time $O(|V| + |E|)$.

bool PLANAR(*graph& G, list<edge>& el, bool embed = false*)

PLANAR takes as input a directed graph $G(V, E)$ and performs a planarity test for G . PLANAR returns true if G is planar and false otherwise. If G is not planar a Kuratowski-Subgraph is computed and returned in *el*.

bool CHECK_KURATOWSKI(*const graph& G, const list<edge>& el*)

returns *true* if all edges in *el* are edges of G and if the edges in *el* form a Kuratowski subgraph of G , returns *false* otherwise. Writes diagnostic output to *cerr*.

- int* KURATOWSKI(*graph*& G , *list*<*node*>& V , *list*<*edge*>& E ,
node_array<*int*>& deg)
 KURATOWSKI computes a Kuratowski subdivision K of G as follows. V is the list of all nodes and subdivision points of K . For all $v \in V$ the degree $deg[v]$ is equal to 2 for subdivision points, 4 for all other nodes if K is a K_5 , and -3 (+3) for the nodes of the left (right) side if K is a $K_{3,3}$. E is the list of all edges in the Kuratowski subdivision.
- list*<*edge*> TRIANGULATE_PLANAR_MAP(*graph*& G)
 TRIANGULATE_PLANAR_MAP takes a directed graph G representing a planar map. It triangulates the faces of G by inserting additional edges. The list of inserted edges is returned.
Precondition: G must be connected.
 The algorithm ([47]) has running time $O(|V| + |E|)$.
- void* FIVE_COLOR(*graph*& G , *node_array*<*int*>& C)
 colors the nodes of G using 5 colors, more precisely, computes for every node v a color $C[v] \in \{0, \dots, 4\}$, such that $C[source(e)] \neq C[target(e)]$ for every edge e . *Precondition:* G is planar. **Remark:** works also for many (sparse ?) non-planar graph.
- void* INDEPENDENT_SET(*const graph*& G , *list*<*node*>& I)
 determines an independent set of nodes I in G . Every node in I has degree at most 9. If G is planar and has no parallel edges then I contains at least $n/6$ nodes.
- bool* IS_CCW_Ordered(*const graph*& G , *const node_array*<*int*>& x ,
const node_array<*int*>& y)
 checks whether the cyclic adjacency list of any node v agrees with the counter-clockwise ordering of the neighbors of v around v defined by their geometric positions.
- bool* SORT_EDGES(*graph*& G , *const node_array*<*int*>& x ,
const node_array<*int*>& y)
 reorders all adjacency lists such the cyclic adjacency list of any node v agrees with the counter-clockwise order of v 's neighbors around v defined by their geometric positions. The function returns true if G is a plane map after the call.

bool *IsCCW_Ordered*(*const graph& G*, *const edge_array<int>& dx*,
 const edge_array<int>& dy)

checks whether the cyclic adjacency list of any node *v* agrees with the counter-clockwise ordering of the neighbors of *v* around *v*. The direction of edge *e* is given by the vector (*dx(e)*, *dy(e)*).

bool *SortEdges*(*graph& G*, *const edge_array<int>& dx*,
 const edge_array<int>& dy)

reorders all adjacency lists such the cyclic adjacency list of any node *v* agrees with the counter-clockwise order of *v*'s neighbors around *v*. The direction of edge *e* is given by the vector (*dx(e)*, *dy(e)*). The function returns true if *G* is a plane map after the call.

13.14 Graph Drawing Algorithms (`graph_draw`)

This section gives a summary of the graph drawing algorithms contained in LEDA. Before using them the header file `<LEDA/graph/graph_draw.h>` has to be included.

int `STRAIGHT_LINE_EMBED_MAP`(*graph*& *G*, *node_array*<*int*>& *xcoord*,
 node_array<*int*>& *ycoord*)

`STRAIGHT_LINE_EMBED_MAP` takes as argument a graph *G* representing a planar map. It computes a straight line embedding of *G* by assigning non-negative integer coordinates (*xcoord* and *ycoord*) in the range $0..2(n - 1)$ to the nodes. `STRAIGHT_LINE_EMBED_MAP` returns the maximal coordinate. The algorithm ([31]) has running time $O(|V|^2)$.

int `STRAIGHT_LINE_EMBEDDING`(*graph*& *G*, *node_array*<*int*>& *xc*,
 node_array<*int*>& *yc*)

`STRAIGHT_LINE_EMBEDDING` takes as argument a planar graph *G* and computes a straight line embedding of *G* by assigning non-negative integer coordinates (*xcoord* and *ycoord*) in the range $0..2(n - 1)$ to the nodes. The algorithm returns the maximal coordinate and has running time $O(|V|^2)$.

bool `VISIBILITY_REPRESENTATION`(*graph*& *G*, *node_array*<*double*>& *x_pos*,
 node_array<*double*>& *y_pos*,
 node_array<*double*>& *x_rad*,
 node_array<*double*>& *y_rad*,
 edge_array<*double*>& *x_sanch*,
 edge_array<*double*>& *y_sanch*,
 edge_array<*double*>& *x_tanch*,
 edge_array<*double*>& *y_tanch*)

computes a visibility representation of the graph *G*, i.e., each node is represented by a horizontal segment (or box) and each edge is represented by a vertical segment.

Precondition: *G* must be planar and has to contain at least three nodes.

- bool* TUTTE_EMBEDDING(*const graph*& *G*, *const list*<*node*>& *fixed_nodes*,
node_array<*double*>& *xpos*,
node_array<*double*>& *ypos*)
 computes a convex drawing of the graph *G* if possible. The list *fixed_nodes* contains nodes with prescribed coordinates already given in *xpos* and *ypos*. The computed node positions of the other nodes are stored in *xpos* and *ypos*, too. If the operation is successful, true is returned.
- void* SPRING_EMBEDDING(*const graph*& *G*, *node_array*<*double*>& *xpos*,
node_array<*double*>& *ypos*, *double* *xleft*,
double *xright*, *double* *ybottom*, *double* *ytop*,
int *iterations* = 250)
 computes a straight-line spring embedding of *G* in the given rectangular region. The coordinates of the computed node positions are returned in *xpos* and *ypos*.
- void* SPRING_EMBEDDING(*const graph*& *G*, *const list*<*node*>& *fixed*,
node_array<*double*>& *xpos*,
node_array<*double*>& *ypos*, *double* *xleft*,
double *xright*, *double* *ybottom*, *double* *ytop*,
int *iterations* = 250)
 as above, however, the positions of all nodes in the *fixed* list is not changed.
- void* D3_SPRING_EMBEDDING(*const graph*& *G*, *node_array*<*double*>& *xpos*,
node_array<*double*>& *ypos*,
node_array<*double*>& *zpos*, *double* *xmin*,
double *xmax*, *double* *ymin*, *double* *ymax*,
double *zmin*, *double* *zmax*,
int *iterations* = 250)
 computes a straight-line spring embedding of *G* in the 3-dimensional space. The coordinates of the computed node positions are returned in *xpos*, *ypos*, and *zpos*.
- int* ORTHO_EMBEDDING(*const graph*& *G*,
const node_array<*bool*>& *crossing*,
const edge_array<*int*>& *maxbends*,
node_array<*int*>& *xcoord*,
node_array<*int*>& *ycoord*, *edge_array*<*list*<*int*>
 >& *xbends*, *edge_array*<*list*<*int*> >& *ybends*)
 Produces an orthogonal (Tamassia) embedding such that each edge *e* has at most *maxbends*[*e*] bends. Returns *true* if such an embedding exists and false otherwise. *Precondition*: *G* must be a planar 4-graph.

- int* `ORTHO_EMBEDDING(const graph& G, node_array<int>& xpos,`
 `node_array<int>& ypos, edge_array<list<int>`
 `>& xbends, edge_array<list<int> >& ybends)`
 as above, but with unbounded number of edge bends.
- bool* `ORTHO_DRAW(const graph& G0, node_array<double>& xpos,`
 `node_array<double>& ypos, node_array<double>& xrad,`
 `node_array<double>& yrad, edge_array<list<double>`
 `>& xbends, edge_array<list<double> >& ybends,`
 `edge_array<double>& xsanch,`
 `edge_array<double>& ysanch,`
 `edge_array<double>& xtanch,`
 `edge_array<double>& ytanch)`
 computes a orthogonal drawing of an arbitrary planar
 graph (nodes of degree larger than 4 are allowed) in the
 so-called Giotto-Model, i.e. high-degree vertices (of
 degree greater than 4) will be represented by larger
 rectangles.
- bool* `SP_EMBEDDING(graph& G, node_array<double>& x_coord,`
 `node_array<double>& y_coord,`
 `node_array<double>& x_radius,`
 `node_array<double>& y_radius, edge_array<list<double>`
 `>& x_bends, edge_array<list<double> >& y_bends,`
 `edge_array<double>& x_sanch,`
 `edge_array<double>& y_sanch,`
 `edge_array<double>& x_tanch,`
 `edge_array<double>& y_tanch)`
 computes a series-parallel drawing of G .
 Precondition: G must be a series-parallel graph.

13.15 Graph Morphism Algorithms (graph_morphism)

1. Definition

An instance `alg` of the parameterized data type `graph_morphism< graph_t, impl >` is an algorithm object that supports finding graph isomorphisms, subgraph isomorphisms, graph monomorphisms and graph automorphisms. The first parameter type parametrizes the input graphs' types. It defaults to `graph`. The second parameter type determines the actual algorithm implementation to use. There are two implementations available so far which work differently well for certain types of graphs. More details can be found in the report *Graph Isomorphism Implementation for LEDA* by Johannes Singler. It is available from our homepage. You can also contact our support team to get it: support@algorithmic-solutions.com resp. support@quappa.com.

```
#include < LEDA/graph/graph_morphism.h >
```

2. Implementation

Allowed implementations parameters are `vf2<graph_t>` and `conauto<graph_t, ord_t>`.

3. Example

```
#include <LEDA/graph/graph_morphism.h>

// declare the input graphs.
graph g1, g2;

// In order to use node compatibility, declare associated node maps for the
// attributes and a corresponding node compatibility function
// (exemplary, see above for the definition of identity_compatibility).

node_map<int> nm1(g1), nm2(g2);
identity_compatibility<int> ic(nm1, nm2);

// do something useful to build up the graphs and the attributes

// instantiate the algorithm object
graph_morphism<graph, conauto<graph> > alg;

// declare the node and edge mapping arrays
node_array<node> node_mapping(g2);
edge_array<edge> edge_mapping(g2);

// prepare a graph morphism data structure for the first graph.
```

```

graph_morphism_algorithm<>::prep_graph pg1 = alg.prepare_graph(g1, ic);

// find the graph isomorphism.
bool isomorphic = alg.find_iso(pg1, g2, &node_mapping, &edge_mapping, ic);

// delete the prepared graph data structure again.
alg.delete_prepared_graph(pg1);

```

Please see `demo/graph_iso/gw_isomorphism.cpp` for an interactive demo program.

13.16 Graph Morphism Algorithm Functionality (`graph_morphism_algorithm`)

1. Types

```

#include < LEDA/graph/graph_morphism_algorithm.h >

graph_morphism_algorithm< graph_t >::node
    the type of an input graph node

graph_morphism_algorithm< graph_t >::edge
    the type of an input graph edge

graph_morphism_algorithm< graph_t >::node_morphism
    the type for a found node mapping

graph_morphism_algorithm< graph_t >::edge_morphism
    the type for a found edge mapping

graph_morphism_algorithm< graph_t >::node_compat
    the type for a node compatibility functor

graph_morphism_algorithm< graph_t >::edge_compat
    the type for an edge compatibility functor

graph_morphism_algorithm< graph_t >::morphism
    the type for a found node and edge mapping

graph_morphism_algorithm< graph_t >::morphism_list
    the type of a list of all found morphisms

graph_morphism_algorithm< graph_t >::callback
    the type for the callback functor

graph_morphism_algorithm< graph_t >::cardinality_t
    the number type of the returned cardinality

```

graph_morphism_algorithm< *graph_t* >::*prep_graph*

the type of a prepared graph data structure

2. Operations

prep_graph *alg.prepare_graph*(*const graph_t*& *g*, *const node_compat*& *node_comp* =
DEFAULT_NODE_CMP,
const edge_compat& *edge_comp* =
DEFAULT_EDGE_CMP)

prepares a data structures of a graph to be used as input to subsequent morphism search calls. This may speed up computation if the same graph is used several times.

void *alg.delete_prepared_graph*(*prep_graph pg*)

frees the memory allocated to a prepared graph data structure constructed before.

cardinality_t *alg.get_num_calls*() returns the number of recursive calls the algorithm has made so far.

void *alg.reset_num_calls*() resets the number of recursive calls to 0.

bool *alg.find_iso*(*const graph_t*& *g1*, *const graph_t*& *g2*,
node_morphism **_node_morph* = *NULL*,
edge_morphism **_edge_morph* = *NULL*,
const node_compat& *_node_comp* = *DEFAULT_NODE_CMP*,
const edge_compat& *_edge_comp* = *DEFAULT_EDGE_CMP*)

searches for a graph isomorphism between *g1* and *g2* and returns it through *node_morph* and *edge_morph* if a non-NULL pointer to a node map and a non-NULL pointer to an edge map are passed respectively. Those must be initialized to *g2* and will therefore carry references to the mapped node or edge in *g1*. The possible mappings can be restricted by the node and edge compatibility functors *node_comp* and *edge_comp*. This method can be called with prepared graph data structures as input for either graph, too.

```
cardinality_t alg.cardinality_iso(const graph_t& g1, const graph_t& g2,  

const node_compat& _node_comp =  

DEFAULT_NODE_CMP,  

const edge_compat& _edge_comp =  

DEFAULT_EDGE_CMP)
```

searches for a graph isomorphism between **g1** and **g2** and returns its cardinality. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**. This method can be called with prepared graph data structures as input for either graph, too.

```
cardinality_t alg.find_allIso(const graph_t& g1, const graph_t& g2,  

list<morphism *>& _isomorphisms,  

const node_compat& _node_comp = DEFAULT_NODE_CMP,  

const edge_compat& _edge_comp = DEFAULT_EDGE_CMP)
```

searches for all graph isomorphisms between **g1** and **g2** and returns them through **_isomorphisms**. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**. This method can be called with prepared graph data structures as input for either graph, too.

```
cardinality_t alg.enumerate_iso(const graph_t& g1, const graph_t& g2,  

leda_callback_base<morphism>& _callback,  

const node_compat& _node_comp =  

DEFAULT_NODE_CMP,  

const edge_compat& _edge_comp =  

DEFAULT_EDGE_CMP)
```

searches for all graph isomorphisms between **g1** and **g2** and calls the callback functor **callb** for each one. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**. This method can be called with prepared graph data structures as input for either graph, too.

```
bool      alg.find_sub(const graph_t& g1, const graph_t& g2,
                    node_morphism * _node_morph = NULL,
                    edge_morphism * _edge_morph = NULL,
                    const node_compat& _node_comp = DEFAULT_NODE_CMP,
                    const edge_compat& _edge_comp = DEFAULT_EDGE_CMP)
```

searches for a subgraph isomorphism from **g2** to **g1** and returns it through **node_morph** and **edge_morph** if a non-NULL pointer to a node map and a non-NULL pointer to an edge map are passed respectively. Those must be initialized to **g2** and will therefore carry references to the mapped node or edge in **g1**. **g2** must not have more nodes or more edges than **g1** to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**. This method can be called with prepared graph data structures as input for either graph, too.

```
cardinality_t alg.cardinality_sub(const graph_t& g1, const graph_t& g2,
                                const node_compat& _node_comp =
                                DEFAULT_NODE_CMP,
                                const edge_compat& _edge_comp =
                                DEFAULT_EDGE_CMP)
```

searches for a subgraph isomorphism from **g2** to **g1** and returns its cardinality. **g2** must not have more nodes or more edges than **g1** to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**. This method can be called with prepared graph data structures as input for either graph, too.

```
cardinality_t alg.findAllSub(const graph_t& g1, const graph_t& g2,
                             list<morphism * >& _isomorphisms,
                             const node_compat& _node_comp =
                             DEFAULT_NODE_CMP, const edge_compat& _edge_comp =
                             DEFAULT_EDGE_CMP)
```

searches for all subgraph isomorphisms from **g2** to **g1** and returns them through **_isomorphisms**. **g2** must not have more nodes or more edges than **g1** to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**. This method can be called with prepared graph data structures as input for either graph, too.

```
cardinality_t alg.enumerate_sub(const graph_t& g1, const graph_t& g2,  

leda_callback_base<morphism>& _callback,  

const node_compat& _node_comp =  

DEFAULT_NODE_CMP,  

const edge_compat& _edge_comp =  

DEFAULT_EDGE_CMP)
```

searches for all subgraph isomorphisms from *g2* to *g1* and calls the callback functor `callb` for each one. *g2* must not have more nodes or more edges than *g1* to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors `node_comp` and `edge_comp`. This method can be called with prepared graph data structures as input for either graph, too.

```
bool alg.find_mono(const graph_t& g1, const graph_t& g2,  

node_morphism * _node_morph = NULL,  

edge_morphism * _edge_morph = NULL,  

const node_compat& _node_comp = DEFAULT_NODE_CMP,  

const edge_compat& _edge_comp = DEFAULT_EDGE_CMP)
```

searches for a graph monomorphism from *g2* to *g1* and returns it through `node_morph` and `edge_morph` if a non-NULL pointer to a node map and a non-NULL pointer to an edge map are passed respectively. Those must be initialized to *g2* and will therefore carry references to the mapped node or edge in *g1*. *g2* must not have more nodes or more edges than *g1* to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors `node_comp` and `edge_comp`. This method can be called with prepared graph data structures as input for either graph, too.

```
cardinality_t alg.cardinality_mono(const graph_t& g1, const graph_t& g2,  

const node_compat& _node_comp =  

DEFAULT_NODE_CMP,  

const edge_compat& _edge_comp =  

DEFAULT_EDGE_CMP)
```

searches for a graph monomorphism from *g2* to *g1* and returns its cardinality. *g2* must not have more nodes or more edges than *g1* to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors `node_comp` and `edge_comp`. This method can be called with prepared graph data structures as input for either graph, too.

```

cardinality_t alg.find_all_mono(const graph_t& g1, const graph_t& g2,
                               list<morphism *>& _isomorphisms,
                               const node_compat& _node_comp =
                               DEFAULT_NODE_CMP,
                               const edge_compat& _edge_comp =
                               DEFAULT_EDGE_CMP)

```

searches for all graph monomorphisms from **g2** to **g1** and returns them through **_isomorphisms**. **g2** must not have more nodes or more edges than **g1** to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**. This method can be called with prepared graph data structures as input for either graph, too.

```

cardinality_t alg.enumerate_mono(const graph_t& g1, const graph_t& g2,
                                 leda_callback_base<morphism>& _callback,
                                 const node_compat& _node_comp =
                                 DEFAULT_NODE_CMP,
                                 const edge_compat& _edge_comp =
                                 DEFAULT_EDGE_CMP)

```

searches for all graph monomorphisms from **g2** to **g1** and calls the callback functor **callb** for each one. **g2** must not have more nodes or more edges than **g1** to make a mapping possible. The possible mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**.

This method can be called with prepared graph data structures as input for either graph, too.

```

bool alg.is_graph_isomorphism(const graph_t& g1, const graph_t& g2,
                              node_morphism const * node_morph,
                              edge_morphism const * edge_morph = NULL,
                              const node_compat& node_comp =
                              DEFAULT_NODE_CMP,
                              const edge_compat& edge_comp =
                              DEFAULT_EDGE_CMP)

```

checks whether the morphism given by **node_morph** and **edge_morph** (optional) is a valid graph isomorphisms between **g1** and **g2**. The allowed mappings can be restricted by the node and edge compatibility functors **node_comp** and **edge_comp**.

Chapter 14

Graphs and Iterators

14.1 Introduction

14.1.1 Iterators

Iterators are a powerful technique in object-oriented programming and one of the fundamental design patterns [39]. Roughly speaking, an iterator is a small, light-weight object, which is associated with a specific kind of linear sequence. An iterator can be used to access all items in a linear sequence step-by-step. In this section, different iterator classes are introduced for traversing the nodes and the edges of a graph, and for traversing all ingoing and/or outgoing edges of a single node.

Iterators are an alternative to the iteration macros introduced in sect. 12.1.3.(i). For example, consider the following iteration pattern:

```
node v;  
forall_nodes (n, G) { ... }
```

Using the class *NodeIt* introduced in sect. 14.2, this iteration can be re-written as follows:

```
for (NodeIt it (G); it.valid(); ++it) { ... }
```

The crucial differences are:

- Iterators provide an intuitive means of movement through the topology of a graph.

- Iterators are not bound to a loop, which means that the user has finer control over the iteration process. For example, the continuation condition *it.valid()* in the above loop could be replaced by another condition to terminate the loop once a specific node has been found (and the loop may be re-started at the same position later on).
- The meaning of iteration may be modified seamlessly. For example, the filter iterators defined in sect. 14.9 restrict the iteration to a subset that is specified by an arbitrary logical condition (*predicate*). In other words, the nodes or edges that do not fulfill this predicate are filtered out automatically during iteration.
- The functionality of iteration may be extended seamlessly. For example, the observer iterators defined in sect. 14.11 can be used to record details of the iteration. A concrete example is given in sect. 14.11: an observer iterator can be initialized such that it records the number of iterations performed by the iterator.
- Iterator-based implementations of algorithms can be easily integrated into environments that are implemented according to the STL style [69], (this style has been adopted for the standard C++ library). For this purpose, sect. 14.12 define adapters, which convert graph iterators into STL iterators.

14.1.2 Handles and Iterators

Iterators can be used whenever the corresponding handle can be used. For example, node iterators can be used where a node is requested or edge iterators can be used where an edge is requested. For adjacency iterators, it is possible to use them whenever an edge is requested¹.

An example shows how iterators can be used as handles:

```
NodeIt it(G);
leda::node_array<int> index(G);
leda::node v;
int i=0;
forall_nodes(v,G) index[v]=++i;
while (it.valid()) {
    cout << "current node " << index(it) << endl; }
```

14.1.3 STL Iterators

Those who are more used to STL may take advantage from the following iterator classes: `NodeIt_n`, `EdgeIt_e`, `AdjIt_n`, `AdjIt_e`, `OutAdjIt_n`, `OutAdjIt_e`, `InAdjIt_n`, `InAdjIt_e`.

¹Since the edge of an adjacency iterator changes while the fixed node remains fixed, we decided to focus on the edge.

The purpose of each iterator is the same as in the corresponding standard iterator classes `NodeIt`, `EdgeIt` . . . The difference is the interface, which is exactly that of the STL iterator wrapper class (see sect. 14.12 for more information).

An example shows why these classes are useful (remember the example from the beginning):

```
NodeIt_n base(G);
for(NodeIt_n::iterator it=base.begin();it!=base.end(); ++it) {
    cout << "current node " << index(*it) << endl; }
```

As in STL collections there are public type definitions in all STL style graph iterators. The advantage is that algorithms can be written that operate independently of the underlying type (note: `NodeIt_n` and `NodeIt_n::iterator` are equal types).

14.1.4 Circulators

Circulators differ from Iterators in their semantics. Instead of becoming invalid at the end of a sequence, they perform cyclic iteration. This type of "none-ending-iterator" is heavily used in the CGAL .

14.1.5 Data Accessors

Data accessor is a design pattern[71] that decouples data access from underlying implementation. Here, the pattern is used to decouple data access in graph algorithms from how data is actually stored outside the algorithm.

Generally, an attributed graph consists of a (directed or undirected) graph and an arbitrary number of node and edge attributes. For example, the nodes of a graph are often assigned attributes such as names, flags, and coordinates, and likewise, the edges are assigned attributes such as lengths, costs, and capacities.

More formally, an *attribute* a of a set S has a certain type T and assigns a value of T to every element of S (in other words, a may be viewed as a function $a : S \rightarrow T$). An *attributed set* $A = (S, a_1, \dots, a_m)$ consists of a set S and attributes a_1, \dots, a_m . An attributed graph is a (directed or undirected) graph $G = (V, E)$ such that the node set V and the edge set E are attributed.

Basically, LEDA provides two features to define attributes for graph:

- Classes *GRAPH* and *UGRAPH* (sects. 12.2 and 12.5) are templates with two arguments, *vtype* and *etype*, which are reserved for a node and an edge attribute, respectively. To attach several attributes to nodes and edges, *vtype* and *etype* must be instantiated by structs whose members are the attributes.
- A *node array* (sect. 12.8) or *node map* (sect. Node Maps) represents a node attribute, and analogously, *edge arrays* (sect. Edge Arrays) and *edge maps* (sect. 12.12), represent edge attributes. Several attributes can be attached to nodes and edges by instantiating several arrays or maps.

Data accessors provide a uniform interface to access attributes, and the concrete organization of the attributes is hidden behind this interface. Hence, if an implementation of an algorithm does not access attributes directly, but solely in terms of data accessors, it may be applied to any organization of the attributes (in contrast, the algorithms in sect. Graph Algorithms require an organization of all attributes as node and edge arrays).

Every data accessor class *DA* comes with a function template *get*:

```
T get(DA da, Iter it);
```

This function returns the value of the attribute managed by the data accessor *da* for the node or edge marked by the iterator *it*. Moreover, most data accessor classes also come with a function template *set*:

```
void set(DA da, Iter it, T value);
```

This function overwrites the value of the attribute managed by the data accessor *da* for the node or edge marked by the iterator *it* by *value*.

The data accessor classes that do not provide a function template *set* realize attributes in such a way that a function *set* does not make sense or is even impossible. The *constant accessor* in sect. 14.14 is a concrete example: it realizes an attribute that is constant over the whole attributed set and over the whole time of the program. Hence, it does not make sense to provide a function *set*. Moreover, since the constant accessor class organizes its attribute in a non-materialized fashion, an overwriting function *set* is even impossible.

Example: The following trivial algorithm may serve as an example to demonstrate the usage of data accessors and their interplay with various iterator types. The first, nested loop accesses all edges once. More specifically, the outer loop iterates over all nodes of the graph, and the inner loop iterates over all edges leaving the current node of the outer loop. Hence, for each edge, the value of the attribute managed by the data accessor *da* is overwritten by *t*. In the second loop, a linear edge iterator is used to check whether the first loop has set all values correctly.

```

template <class T, class DA>
void set_and_check (graph& G, DA da, T t) {
    for (NodeIt nit(G); nit.valid(); ++nit)
        for (OutAdjIt oait(nit); oait.valid(); ++oait)
            set (da, eit, t);
    for (EdgeIt eit(G); eit.valid(); ++eit)
        if (get(da,eit) != t) cout << "Error!" << endl;
}

```

To demonstrate the application of function *set_and_check*, we first consider the case that *G* is an object of the class *GRAPH* derived from *graph* (sect. 12.1), that the template argument *vtype* is instantiated by a struct type *attributes*, and that the *int*-member *my_attr* of *attributes* shall be processed by *set_and_check* with value 1. Then *DA* can be instantiated as a *node_member_da*:

```

node_member_da<attributes,int> da (&attributes::my_attr);
set_and_check (G, da, 1);

```

Now we consider the case that the attribute to be processed is stored in an *edge_array<int>* named *my_attr_array*:

```

node_array_da<int> da (my_attr_array);
set_and_check (G, da, 1);

```

Hence, all differences between these two cases are factored out into a single declaration statement.

14.1.6 Graphiterator Algorithms

Several basic graph algorithms were re-implemented to use only graph iterators and data accessors. Moreover they share three design decisions:

1. **algorithms are instances** of classes
2. algorithm instances have the **ability to “advance”**
3. algorithm instances provide **access to their internal states**

An example for an algorithm that supports the first two decisions is:

```
class Algorithm {
    int state, endstate;
public:
    Algorithm(int max) : endstate(max), state(0) { }
    void next() { state++; }
    bool finished() { return state>=endstate; }
};
```

With this class `Algorithm` we can easily instantiate an algorithm object:

```
Algorithm alg(5);
while (!alg.finished()) alg.next();
```

This small piece of code creates an algorithm object and invokes “`next()`” until it has reached an end state.

An advantage of this design is that we can write basic algorithms, which can be used in a standardized way and if needed, inspection of internal states and variables can be provided without writing complex code. Additionally, it makes it possible to write persistent algorithms, if the member variables are persistent.

Actually, those algorithms are quite more flexible than ordinary written algorithm functions:

```
template<class Alg>
class OutputAlg {
    Alg alg;
public:
    OutputAlg(int m) : alg(m) {
        cout << "max state: " << m << endl; }
    void next() {
        cout << "old state: " << alg.state;
        alg.next();
        cout << " new state: " << alg.state << endl; }
    bool finished() { return alg.finished(); }
};
```

This wrapper algorithm can be used like this:

```
OutputAlg<Algorithm> alg(5);
while (!alg.finished()) alg.next();
```

In addition to the algorithm mentioned earlier this wrapper writes the internal states to the standard output.

This is as efficient as rewriting the “Algorithm”-class with an output mechanism, but provides more flexibility.

14.2 Node Iterators (NodeIt)

1. Definition

a variable *it* of class *NodeIt* is a linear node iterator that iterates over the node set of a graph; the current node of an iterator object is said to be “marked” by this object.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

NodeIt it; introduces a variable *it* of this class associated with no graph.

NodeIt it(const leda::graph& G);

introduces a variable *it* of this class associated with *G*.
The graph is initialized by *G*. The node is initialized by *G.first_node()*.

NodeIt it(const leda::graph& G, leda::node n);

introduces a variable *it* of this class marked with *n* and associated with *G*.
Precondition: *n* is a node of *G*.

3. Operations

void it.init(const leda::graph& G)

associates *it* with *G* and marks it with *G.first_node()*.

void it.init(const leda::graph& G, const leda::node& v)

associates *it* with *G* and marks it with *v*.

void it.reset()

resets *it* to *G.first_node()*, where *G* is the associated graph.

void it.make_invalid()

makes *it* invalid, i.e. *it.valid()* will be false afterwards and *it* marks no node.

void it.reset_end()

resets *it* to *G.last_node()*, where *G* is the associated graph.

<i>void</i>	<i>it.update(leda::node n)</i>	<i>it</i> marks <i>n</i> afterwards.
<i>void</i>	<i>it.insert()</i>	creates a new node and <i>it</i> marks it afterwards.
<i>void</i>	<i>it.del()</i>	deletes the marked node, i.e. <i>it.valid()</i> returns false afterwards. Precondition: <i>it.valid()</i> returns true.
<i>NodeIt&</i>	<i>it = const NodeIt& it2</i>	<i>it</i> is afterwards associated with the same graph and node as <i>it2</i> . This method returns a reference to <i>it</i> .
<i>bool</i>	<i>it == const NodeIt& it2</i>	returns true if and only if <i>it</i> and <i>it2</i> are equal, i.e. if the marked nodes are equal.
<i>leda::node</i>	<i>it.get_node()</i>	returns the marked node or nil if <i>it.valid()</i> returns false.
<i>const leda::graph&</i>	<i>it.get_graph()</i>	returns the associated graph.
<i>bool</i>	<i>it.valid()</i>	returns true if and only if end of sequence not yet passed, i.e. if there is a node in the node set that was not yet passed.
<i>bool</i>	<i>it.eol()</i>	returns <i>!it.valid()</i> which is true if and only if there is no successor node left, i.e. if all nodes of the node set are passed (eol: end of list).
<i>NodeIt&</i>	<i>++it</i>	performs one step forward in the list of nodes of the associated graph. If there is no successor node, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.
<i>NodeIt&</i>	<i>--it</i>	performs one step backward in the list of nodes of the associated graph. If there is no predecessor node, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.

4. Implementation

Creation of an iterator and all methods take constant time.

14.3 Edge Iterators (EdgeIt)

1. Definition

a variable *it* of class *EdgeIt* is a linear edge iterator that iterates over the edge set of a graph; the current edge of an iterator object is said to be “marked” by this object.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

EdgeIt it; introduces a variable *it* of this class associated with no graph.

EdgeIt it(const leda::graph& G);
introduces a variable *it* of this class associated with *G* and marked with *G.first_edge()*.

EdgeIt it(const leda::graph& G, leda::edge e);
introduces a variable *it* of this class marked with *e* and associated with *G*.
Precondition: *e* is an edge of *G*.

3. Operations

void it.init(const leda::graph& G)
associates *it* with *G* and marks it with *G.first_edge()*.

void it.init(const leda::graph& G, const leda::edge& e)
associates *it* with *G* and marks it with *e*.

void it.update(leda::edge e)
it marks *e* afterwards.

void it.reset() resets *it* to *G.first_edge()* where *G* is the associated graph.

void it.reset_end() resets *it* to *G.last_edge()* where *G* is the associated graph.

void it.make_invalid() makes *it* invalid, i.e. *it.valid()* will be false afterwards and *it* marks no node.

void it.insert(leda::node v1, leda::node v2)
creates a new edge from *v1* to *v2* and *it* marks it afterwards.

void it.del() deletes the marked edge, i.e. *it.valid()* returns false afterwards.
Precondition: *it.valid()* returns true.

<i>EdgeIt&</i>	<i>it = const EdgeIt& it2</i>	assigns <i>it2</i> to <i>it</i> . This method returns a reference to <i>it</i> .
<i>bool</i>	<i>it == const EdgeIt& it2</i>	returns true if and only if <i>it</i> and <i>it2</i> are equal, i.e. if the marked edges are equal.
<i>bool</i>	<i>it.eol()</i>	returns <i>!it.valid()</i> which is true if and only if there is no successor edge left, i.e. if all edges leaving the marked node are passed (eol: end of list).
<i>bool</i>	<i>it.valid()</i>	returns true if and only if end of sequence not yet passed, i.e. if there is an edge leaving the marked node that was not yet passed.
<i>leda::edge</i>	<i>it.get_edge()</i>	returns the marked edge or nil if <i>it.valid()</i> returns false.
<i>const leda::graph&</i>	<i>it.get_graph()</i>	returns the associated graph.
<i>EdgeIt&</i>	<i>++it</i>	performs one step forward in the list of edges of the associated graph. If there is no successor edge, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.
<i>EdgeIt&</i>	<i>--it</i>	performs one step backward in the list of edges of the associated graph. If there is no predecessor edge, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.

4. Implementation

Creation of an iterator and all methods take constant time.

14.4 Face Iterators (**FaceIt**)

1. Definition

a variable *it* of class *FaceIt* is a linear face iterator that iterates over the face set of a graph; the current face of an iterator object is said to be “marked” by this object.

Precondition: Before using any face iterator the list of faces has to be computed by calling *G.compute_faces()*. Note, that any update operation invalidates this list.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

FaceIt *it*; introduces a variable *it* of this class associated with no graph.

```
FaceIt it(const leda::graph& G);
```

introduces a variable *it* of this class associated with *G*.
The graph is initialized by *G*. The face is initialized by *G.first_face()*.

```
FaceIt it(const leda::graph& G, leda::face n);
```

introduces a variable *it* of this class marked with *n* and associated with *G*.

Precondition: *n* is a face of *G*.

3. Operations

```
void           it.init(const leda::graph& G)
```

associates *it* with *G* and marks it with *G.first_face()*.

```
void           it.init(const leda::graph& G, const leda::face& v)
```

associates *it* with *G* and marks it with *v*.

```
void           it.reset()
```

resets *it* to *G.first_face()*, where *G* is the associated graph.

```
void           it.make_invalid()
```

makes *it* invalid, i.e. *it.valid()* will be false afterwards and *it* marks no face.

```
void           it.reset_end()
```

resets *it* to *G.last_face()*, where *G* is the associated graph.

```
void           it.update(leda::face n)
```

it marks *n* afterwards.

```
FaceIt&        it = const FaceIt& it2
```

it is afterwards associated with the same graph and face as *it2*. This method returns a reference to *it*.

```
bool           it == const FaceIt& it2
```

returns true if and only if *it* and *it2* are equal, i.e. if the marked faces are equal.

```
leda::face    it.get_face()
```

returns the marked face or nil if *it.valid()* returns false.

```
const leda::graph& it.get_graph()
```

returns the associated graph.

<i>bool</i>	<i>it.valid()</i>	returns true if and only if end of sequence not yet passed, i.e. if there is a face in the face set that was not yet passed.
<i>bool</i>	<i>it.eol()</i>	returns <i>!it.valid()</i> which is true if and only if there is no successor face left, i.e. if all faces of the face set are passed (eol: end of list).
<i>FaceIt&</i>	<i>++it</i>	performs one step forward in the list of faces of the associated graph. If there is no successor face, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.
<i>FaceIt&</i>	<i>--it</i>	performs one step backward in the list of faces of the associated graph. If there is no predecessor face, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.

4. Implementation

Creation of an iterator and all methods take constant time.

14.5 Adjacency Iterators for leaving edges (*OutAdjIt*)

1. Definition

a variable *it* of class *OutAdjIt* is an adjacency iterator that marks a node (which is fixed in contrast to linear node iterators) and iterates over the edges that leave this node.

There is a variant of the adjacency iterators, so-called circulators which are heavily used in the CGAL². The names of the classes are *OutAdjCirc* and *InAdjCirc* and their interfaces are completely equal to the iterator versions while they internally use e.g. *cyclic_adj_succ()* instead of *adj_succ()*.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

OutAdjIt it; introduces a variable *it* of this class associated with no graph.

²See the CGAL homepage at <http://www.cs.uu.nl/CGAL/>.

OutAdjIt *it*(*const leda::graph& G*);

introduces a variable *it* of this class associated with *G*.
The node is initialized by *G.first_node()* and the edge by *G.first_adj_edge(n)* where *n* is the marked node.

OutAdjIt *it*(*const leda::graph& G, leda::node n*);

introduces a variable *it* of this class marked with *n* and associated with *G*. The marked edge is initialized by *G.first_adj_edge(n)*.
Precondition: *n* is a node of *G*.

OutAdjIt *it*(*const leda::graph& G, leda::node n, leda::edge e*);

introduces a variable *it* of this class marked with *n* and *e* and associated with *G*.
Precondition: *n* is a node and *e* an edge of *G* and *source(e) = n*.

3. Operations

void *it.init(const leda::graph& G)*

associates *it* with *G* and marks it with *n' = G.first_node()* and *G.first_adj_edge(n')*.

void *it.init(const leda::graph& G, const leda::node& n)*

associates *it* with *G* and marks it with *n* and *G.first_adj_edge(n)*.
Precondition: *n* is a node of *G*.

void *it.init(const leda::graph& G, const leda::node& n, const leda::edge& e)*

associates *it* with *G* and marks it with *n* and *e*.
Precondition: *n* is a node and *e* an edge of *G* and *source(e) = n*.

void *it.update(leda::edge e)*

it marks *e* afterwards.

void *it.reset()*

resets *it* to *G.first_adj_edge(n)* where *G* and *n* are the marked node and associated graph.

void *it.insert(const OutAdjIt& other)*

creates a new leaving edge from the marked node of *it* to the marked node of *other*. *it* is marked with the new edge afterwards. The marked node of *it* does not change.

void *it.del()*

deletes the marked leaving edge, i.e. *it.valid()* returns false afterwards.
Precondition: *it.valid()* returns true.

<i>void</i>	<i>it.reset_end()</i>	resets <i>it</i> to <i>G.last_adj_edge(n)</i> where <i>G</i> and <i>n</i> are the marked node and associated graph.
<i>void</i>	<i>it.make_invalid()</i>	makes <i>it</i> invalid, i.e. <i>it.valid()</i> will be false afterwards and <i>it</i> marks no node.
<i>void</i>	<i>it.update(leda::node n)</i>	<i>it</i> marks <i>n</i> and the first leaving edge of <i>n</i> afterwards.
<i>void</i>	<i>it.update(leda::node n, leda::edge e)</i>	<i>it</i> marks <i>n</i> and <i>e</i> afterwards.
<i>OutAdjIt&</i>	<i>it = const OutAdjIt& it2</i>	assigns <i>it2</i> to <i>it</i> . This method returns a reference to <i>it</i> .
<i>bool</i>	<i>it == const OutAdjIt& it2</i>	returns true if and only if <i>it</i> and <i>it2</i> are equal, i.e. if the marked nodes and edges are equal.
<i>bool</i>	<i>it.has_node()</i>	returns true if and only if <i>it</i> marks a node.
<i>bool</i>	<i>it.eol()</i>	returns <i>!it.valid()</i> which is true if and only if there is no successor edge left, i.e. if all edges of the edge set are passed (eol: end of list).
<i>bool</i>	<i>it.valid()</i>	returns true if and only if end of sequence not yet passed, i.e. if there is an edge in the edge set that was not yet passed.
<i>leda::edge</i>	<i>it.get_edge()</i>	returns the marked edge or nil if <i>it.valid()</i> returns false.
<i>leda::node</i>	<i>it.get_node()</i>	returns the marked node or nil if <i>it.has_node()</i> returns false.
<i>const leda::graph&</i>	<i>it.get_graph()</i>	returns the associated graph.
<i>OutAdjIt</i>	<i>it.curr_adj()</i>	returns a new adjacency iterator that is associated with $n' = target(e)$ and <i>G.first_adj_edge(n')</i> where <i>G</i> is the associated graph. Precondition: <i>it.valid()</i> returns true.
<i>OutAdjIt&</i>	<i>++it</i>	performs one step forward in the list of outgoing edges of the marked node. If there is no successor edge, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.

OutAdjIt& `--it` performs one step backward in the list of outgoing edges of the marked node. If there is no predecessor edge, *it.eol()* will be true afterwards. This method returns a reference to *it*.
Precondition: *it.valid()* returns true.

4. Implementation

Creation of an iterator and all methods take constant time.

14.6 Adjacency Iterators for incoming edges (InAdjIt)

1. Definition

a variable *it* of class *InAdjIt* is an adjacency iterator that marks a node (which is fixed in contrast to linear node iterators) and iterates over the incoming edges of this node.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

InAdjIt *it*; introduces a variable *it* of this class associated with no graph.

InAdjIt *it*(*const leda::graph& G*);
introduces a variable *it* of this class associated with *G*.
The node is initialized by *G.first_node()* and the edge by *G.first_in_edge(n)* where *n* is the marked node.

InAdjIt *it*(*const leda::graph& G, leda::node n*);
introduces a variable *it* of this class marked with *n* and associated with *G*. The marked edge is initialized by *G.first_in_edge(n)*.
Precondition: *n* is a node of *G*.

InAdjIt *it*(*const leda::graph& G, leda::node n, leda::edge e*);
introduces a variable *it* of this class marked with *n* and *e* and associated with *G*.
Precondition: *n* is a node and *e* an edge of *G* and *target(e) = n*.

3. Operations

void *it.init(const leda::graph& G)*
associates *it* with *G* and marks it with *n' = G.first_node()* and *G.first_adj_edge(n')*.

<i>void</i>	<i>it.init(const leda:: graph& G, const leda:: node& n)</i>	associates <i>it</i> with <i>G</i> and marks it with <i>n</i> and <i>G.first_adj_edge(n)</i> . Precondition: <i>n</i> is a node of <i>G</i> .
<i>void</i>	<i>it.init(const leda:: graph& G, const leda:: node& n, const leda:: edge& e)</i>	associates <i>it</i> with <i>G</i> and marks it with <i>n</i> and <i>e</i> . Precondition: <i>n</i> is a node and <i>e</i> an edge of <i>G</i> and <i>target(e) = n</i> .
<i>void</i>	<i>it.update(leda:: edge e)</i>	<i>it</i> marks <i>e</i> afterwards.
<i>void</i>	<i>it.reset()</i>	resets <i>it</i> to <i>G.first_in_edge(n)</i> where <i>G</i> and <i>n</i> are the marked node and associated graph.
<i>void</i>	<i>it.insert(const InAdjIt& other)</i>	creates a new incoming edge from the marked node of <i>it</i> to the marked node of <i>other</i> . <i>it</i> is marked with the new edge afterwards. The marked node of <i>it</i> does not change.
<i>void</i>	<i>it.del()</i>	deletes the marked incoming edge, i.e. <i>it.valid()</i> returns false afterwards. Precondition: <i>it.valid()</i> returns true.
<i>void</i>	<i>it.reset_end()</i>	resets <i>it</i> to <i>G.last_in_edge(n)</i> where <i>G</i> and <i>n</i> are the marked node and associated graph.
<i>void</i>	<i>it.make_invalid()</i>	makes <i>it</i> invalid, i.e. <i>it.valid()</i> will be false afterwards and <i>it</i> marks no node.
<i>void</i>	<i>it.update(leda:: node n)</i>	<i>it</i> marks <i>n</i> and the first incoming edge of <i>n</i> afterwards.
<i>void</i>	<i>it.update(leda:: node n, leda:: edge e)</i>	<i>it</i> marks <i>n</i> and <i>e</i> afterwards.
<i>InAdjIt&</i>	<i>it = const InAdjIt& it2</i>	assigns <i>it2</i> to <i>it</i> . This method returns a reference this method returns a reference to <i>it</i> .
<i>bool</i>	<i>it == const InAdjIt& it2</i>	returns true if and only if <i>it</i> and <i>it2</i> are equal, i.e. if the marked nodes and edges are equal.
<i>bool</i>	<i>it.has_node()</i>	returns true if and only if <i>it</i> marks a node.

<i>bool</i>	<i>it.eol()</i>	returns <i>!it.valid()</i> which is true if and only if there is no successor edge left, i.e. if all edges of the edge set are passed (eol: end of list).
<i>bool</i>	<i>it.valid()</i>	returns true if and only if end of sequence not yet passed, i.e. if there is an edge in the edge set that was not yet passed.
<i>leda:: edge</i>	<i>it.get_edge()</i>	returns the marked edge or nil if <i>it.valid()</i> returns false.
<i>leda:: node</i>	<i>it.get_node()</i>	returns the marked node or nil if <i>it.has_node()</i> returns false.
<i>const leda:: graph&</i>	<i>it.get_graph()</i>	returns the associated graph.
<i>InAdjIt</i>	<i>it.curr_adj()</i>	returns a new adjacency iterator that is associated with $n' = source(e)$ and $G.first_in_edge(n')$ where G is the associated graph. Precondition: <i>it.valid()</i> returns true.
<i>InAdjIt&</i>	<i>++it</i>	performs one step forward in the list of incoming edges of the marked node. If there is no successor edge, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.
<i>InAdjIt&</i>	<i>--it</i>	performs one step backward in the list of incoming edges of the marked node. If there is no predecessor edge, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.

4. Implementation

Creation of an iterator and all methods take constant time.

14.7 Adjacency Iterators (AdjIt)

1. Definition

a variable *it* of class *AdjIt* is an adjacency iterator that marks a node (which is fixed in contrast to linear node iterators) and iterates over the edges that leave or enter this node. At first, all outgoing edges will be traversed.

Internally, this iterator creates two instances of *OutAdjIt* and *InAdjIt*. The iteration is a sequenced iteration over both iterators. Note that this only fits for directed graph, for undirected graph you should use *OutAdjIt* instead.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

AdjIt *it*; introduces a variable *it* of this class associated with no graph.

AdjIt *it*(*const leda::graph& G*);

introduces a variable *it* of this class associated with *G*. The marked node is initialized by $n = G.first_node()$ and the edge by $G.first_adj_edge(n)$.

AdjIt *it*(*const leda::graph& G*, *leda::node n*);

introduces a variable *it* of this class marked with *n* and associated with *G*. The marked edge is initialized by $G.first_adj_edge(n)$.
Precondition: *n* is a node of *G*.

AdjIt *it*(*const leda::graph& G*, *leda::node n*, *leda::edge e*);

introduces a variable *it* of this class marked with *n* and *e* and associated with *G*.
Precondition: *n* is a node and *e* an edge of *G* and $source(e) = n$.

3. Operations

void *it.init(const graphtype& G)*

associates *it* with *G* and marks it with $n' = G.first_node()$ and $G.first_adj_edge(n')$.

void *it.init(const graphtype& G, const nodetype& n)*

associates *it* with *G* and marks it with *n* and $G.first_adj_edge(v)$.
Precondition: *n* is a node of *G*.

void *it.init(const graphtype& G, const nodetype& n, const edgetype& e)*

associates *it* with *G* and marks it with *n* and *e*.
Precondition: *n* is a node and *e* an edge of *G* and $source(e) = n$.

void *it.update(leda::edge e)*

it marks *e* afterwards.

void *it.reset()*

resets *it* to $G.first_adj_edge(n)$ where *G* and *n* are the marked node and associated graph.

void *it.insert(const AdjIt& other)*

creates a new edge from the marked node of *it* to the marked node of *other*. *it* is marked with the new edge afterwards. The marked node of *it* does not change.

<i>void</i>	<i>it.del()</i>	deletes the marked leaving edge, i.e. <i>it.valid()</i> returns false afterwards. Precondition: <i>it.valid()</i> returns true.
<i>void</i>	<i>it.reset_end()</i>	resets <i>it</i> to <i>G.last_adj_edge(n)</i> where <i>G</i> and <i>n</i> are the marked node and associated graph.
<i>void</i>	<i>it.make_invalid()</i>	makes <i>it</i> invalid, i.e. <i>it.valid()</i> will be false afterwards and <i>it</i> marks no node.
<i>void</i>	<i>it.update(leda::node n)</i>	<i>it</i> marks <i>n</i> and the first leaving edge of <i>n</i> afterwards.
<i>void</i>	<i>it.update(leda::node n, leda::edge e)</i>	<i>it</i> marks <i>n</i> and <i>e</i> afterwards.
<i>AdjIt&</i>	<i>it = const AdjIt& it2</i>	assigns <i>it2</i> to <i>it</i> . This method returns a reference to <i>it</i> .
<i>bool</i>	<i>it == const AdjIt& it2</i>	returns true if and only if <i>it</i> and <i>it2</i> are equal, i.e. if the marked nodes and edges are equal.
<i>bool</i>	<i>it.has_node()</i>	returns true if and only if <i>it</i> marks a node.
<i>bool</i>	<i>it.eol()</i>	returns <i>!it.valid()</i> which is true if and only if there is no successor edge left, i.e. if all edges of the edge set are passed (eol: end of list).
<i>bool</i>	<i>it.valid()</i>	returns true if and only if end of sequence not yet passed, i.e. if there is an edge in the edge set that was not yet passed.
<i>leda::edge</i>	<i>it.get_edge()</i>	returns the marked edge or nil if <i>it.valid()</i> returns false.
<i>leda::node</i>	<i>it.get_node()</i>	returns the marked node or nil if <i>it.has_node()</i> returns false.
<i>const leda::graph&</i>	<i>it.get_graph()</i>	returns the associated graph.
<i>AdjIt</i>	<i>it.curr_adj()</i>	If the currently associated edge leaves the marked node, this method returns a new adjacency iterator that is associated with $n' = target(e)$ and <i>G.first_adj_edge(n')</i> where <i>G</i> is the associated graph. Otherwise it returns a new adjacency iterator that is associated with $n' = source(e)$ and <i>G.first_in_edge(n')</i> where <i>G</i> is the associated graph. Precondition: <i>it.valid()</i> returns true.

<i>AdjIt&</i>	<code>++it</code>	performs one step forward in the list of incident edges of the marked node. If the formerly marked edge was a leaving edge and there is no successor edge, <i>it</i> is associated to <i>G.first_in_edge(n)</i> where <i>G</i> and <i>n</i> are the associated graph and node. If the formerly marked edge was an incoming edge and there is no successor edge, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.
<i>AdjIt&</i>	<code>--it</code>	performs one step backward in the list of incident edges of the marked node. If the formerly marked edge was an incoming edge and there is no predecessor edge, <i>it</i> is associated to <i>G.last_adj_edge(n)</i> where <i>G</i> and <i>n</i> are the associated graph and node. If the formerly marked edge was a leaving edge and there is no successor edge, <i>it.eol()</i> will be true afterwards. This method returns a reference to <i>it</i> . Precondition: <i>it.valid()</i> returns true.

4. Implementation

Creation of an iterator and all methods take constant time.

14.8 Face Circulators (FaceCirc)

1. Definition

a variable *fc* of class *FaceCirc* is a face circulator that circulates through the set of edges of a face as long as the graph is embedded combinatorically correct, i.e. the graph has to be bidirected and a map (see 12.1).

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

FaceCirc fc; introduces a variable *fc* of this class associated with no graph.

FaceCirc fc(const leda::graph& G);
introduces a variable *fc* of this class associated with *G*. The edge is initialized to `nil`.

FaceCirc fc(const leda::graph& G, leda::edge e);
introduces a variable *fc* of this class marked with *e* and associated with *G*.
Precondition: *e* is an edge of *G*.

3. Operations

<i>void</i>	<i>fc.init(const leda:: graph& G)</i>	associates <i>fc</i> with <i>G</i> .
<i>void</i>	<i>fc.init(const leda:: graph& G, const leda:: edge& e)</i>	associates <i>fc</i> with <i>G</i> and marks it with <i>e</i> . Precondition: <i>e</i> is an edge of <i>G</i> .
<i>void</i>	<i>fc.update(leda:: edge e)</i>	<i>fc</i> marks <i>e</i> afterwards.
<i>void</i>	<i>fc.make_invalid()</i>	makes <i>fc</i> invalid, i.e. <i>fc.valid()</i> will be false afterwards and <i>fc</i> marks no edge.
<i>FaceCirc&</i>	<i>fc = const FaceCirc& fc2</i>	assigns <i>fc2</i> to <i>fc</i> . This method returns a reference to <i>fc</i> .
<i>bool</i>	<i>fc == const FaceCirc& fc2</i>	returns true if and only if <i>fc</i> and <i>fc2</i> are equal, i.e. if the marked edges are equal.
<i>bool</i>	<i>fc.has_edge()</i>	returns true if and only if <i>fc</i> marks an edge.
<i>bool</i>	<i>fc.eol()</i>	returns <i>!fc.valid()</i> .
<i>bool</i>	<i>fc.valid()</i>	returns true if and only if the circulator is marked with an edge.
<i>leda:: edge</i>	<i>fc.get_edge()</i>	returns the marked edge or nil if <i>fc.valid()</i> returns false.
<i>const leda:: graph&</i>	<i>fc.get_graph()</i>	returns the associated graph.
<i>FaceCirc&</i>	<i>++fc</i>	redirects the circulator to the cyclic adjacency predecessor of <i>reversal(e)</i> , where <i>e</i> is the marked edge. This method returns a reference to <i>fc</i> . Precondition: <i>fc.valid()</i> returns true.
<i>FaceCirc&</i>	<i>--fc</i>	redirects the circulator to the cyclic adjacency successor of <i>e</i> , where <i>e</i> is the marked edge. This method returns a reference to <i>fc</i> . Precondition: <i>fc.valid()</i> returns true.

4. Implementation

Creation of a circulator and all methods take constant time.

14.9 Filter Node Iterator (`FilterNodeIt`)

1. Definition

An instance *it* of class `FilterNodeIt< Predicate, Iter >` encapsulates an object of type `Iter` and creates a restricted view on the set of nodes over which this internal iterator iterates. More specifically, all nodes that do not fulfill the predicate defined by `Predicate` are filtered out during this traversal.

Class `FilterEdgeIt` and `FilterAdjIt` are defined analogously, i.e. can be used for edge iterators or adjacency iterators, respectively.

Precondition: The template parameter `Iter` must be a node iterator, e.g. `NodeIt` or `FilterNodeIt<pred,NodeIt>`. `Predicate` must be a class which provides a method `operator()` according to the following signature: `bool operator() (Iter)`.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
FilterNodeIt< Predicate, Iter > it;
```

introduces a variable *it* of this class, not bound to a predicate or iterator.

```
FilterNodeIt< Predicate, Iter > it(const Predicate& pred, const Iter& base_it);
```

introduces a variable *it* of this class bound to *pred* and *base_it*.

3. Operations

```
void it.init(const Predicate& pred, const Iter& base_it)
```

initializes *it*, which is bound to *pred* and *base_it* afterwards.

Precondition: *it* is not yet bound to a predicate or iterator.

4. Implementation

Constant overhead.

5. Example

Suppose each node has an own colour and we only want to see those with a specific colour, for example red (we use the LEDA colours). At first the data structures:

```
GRAPH<color,double> G;
NodeIt it(G);
```

We would have to write something like this:

```
while(it.valid()) {
    if (G[it.get_node()]==red) do_something(it);
    ++it;
}
```

With the filter wrapper class we can add the test if the node is red to the behaviour of the iterator.

```
struct RedPred {
    bool operator() (const NodeIt& it) const {
        return G[it.get_node()]==red; }
} redpred;
FilterNodeIt<RedPred,NodeIt> red_it(redpred,it);
```

This simplifies the loop to the following:

```
while(red_it.valid()) {
    do_something(red_it);
    ++red_it; }
```

All ingredients of the comparison are hard-wired in struct `RedPred`: the type of the compared values (`color`), the comparison value (`red`) and the binary comparison (equality). The following class `CompPred` renders these three choices flexible.

14.10 Comparison Predicate (`CompPred`)

1. Definition

An instance *cp* of class `CompPred<Iter, DA, Comp>` is a predicate comparator that produces boolean values with the given compare function and the attribute associated with an iterator.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
CompPred<Iter, DA, Comp> cp(const DA& da, const Comp& comp,
                           typename DA::value_type val);
```

introduces a variable *cp* of this class and associates it to the given data accessor *da*, compare function *comp* and value *val*.

Precondition: *Comp* is a pointer-to-function type which takes two values of type *typename DA::value_type* and produces a boolean return value. *Comp* might also be a class with member function *bool operator() (typename DA::value_type, typename DA::value_type)*.

3. Example

In the following example, a node iterator for red nodes will be created. At first the basic part (see sect. 14.13 for explanation of the data accessor `node_array_da`):

```
graph G;
NodeIt it(G);
node_array<color> na_colour(G,black);
node_array_da<color> da_colour(na_colour);
assign_some_color_to_each_node();
```

Now follows the definition of a “red iterator” (`Equal<T>` yields true, if the given two values are equal):

```
template<class T>
class Equal {
public:
    bool operator() (T t1, T t2) const {
        return t1==t2; }
};

typedef CompPred<NodeIt,node_array_da<color>,Equal<color> > Predicate;
Predicate PredColour(da_colour,Equal<color>(),red);
FilterNodeIt<Predicate,NodeIt> red_it(PredColour,it);
```

This simplifies the loop to the following:

```
while(red_it.valid()) {
    do_something(red_it);
    ++red_it; }
```

`Equal<T>` is a class that compares two items of the template parameter `T` by means of a method `bool operator()(T,T);`. There are some classes available for this purpose: `Equal<T>`, `Unequal<T>`, `LessThan<T>`, `LessEqual<T>`, `GreaterThan<T>` and `GreaterEqual<T>` with obvious semantics, where `T` is the type of the values. Predicates of the STL can be used as well since they have the same interface.

14.11 Observer Node Iterator (`ObserverNodeIt`)

1. Definition

An instance *it* of class `ObserverNodeIt<Obs, Iter>` is an observer iterator. Any method call of iterators will be “observed” by an internal object of class `Obs`.

Class `ObserverEdgeIt` and `ObserverAdjIt` are defined analogously, i.e. can be used for edge iterators or adjacency iterators, respectively.

Precondition: The template parameter `Iter` must be a node iterator.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
ObserverNodeIt<Obs, Iter> it;
```

introduces a variable *it* of this class, not bound to an observer or iterator.

```
ObserverNodeIt<Obs, Iter> it( Obs& obs, const Iter& base_it );
```

introduces a variable *it* of this class bound to the observer *obs* and *base_it*.

Precondition: `Obs` must have methods `observe_constructor()`, `observe_forward()`, `observe_update()`. These three methods may have arbitrary return types (incl. `void`).

3. Operations

```
void it.init( const Obs& obs, const Iter& base_it )
```

initializes *it*, which is bound to *obs* and *base_it* afterwards.

Precondition: *it* is not bound to an observer or iterator.

```
Obs& it.get_observer()
```

returns a reference to the observer to which it is bound.

4. Example

First two simple observer classes. The first one is a dummy class, which ignores all notifications. The second one merely counts the number of calls to `operator++` for all iterators that share the same observer object through copy construction or assignment (of course, a real implementation should apply some kind of reference counting or other garbage collection).

In this example, the counter variable `_count` of class `SimpleCountObserver` will be initialized with the counter variable `_count` of class `DummyObserver`, i.e. the variable is created only once.

```
template <class Iter>
class DummyObserver {
    int* _count;
public:
    DummyObserver() : _count(new int(0)) { }
    void notify_constructor(const Iter& ) { }
    void notify_forward(const Iter& ) { }
    void notify_update(const Iter& ) { }
    int counter() const { return *_count; }
    int* counter_ptr() const { return _count; }
    bool operator==(const DummyObserver& D) const {
        return _count==D._count; }
};

template <class Iter, class Observer>
class SimpleCountObserver {
    int* _count;
public:
    SimpleCountObserver() : _count(new int(0)) { }
    SimpleCountObserver(Observer& obs) :
        _count(obs.counter_ptr()) { }
    void notify_constructor(const Iter& ) { }
    void notify_forward(const Iter& ) { ++(*_count); }
    void notify_update(const Iter& ) { }
    int counter() const { return *_count; }
    int* counter_ptr() const { return _count; }
    bool operator==(const SimpleCountObserver& S) const {
        return _count==S._count; }
};
```

Next an exemplary application, which counts the number of calls to `operator++` of all adjacency iterator objects inside `dummy_algorithm`. Here the dummy observer class is

used only as a “Trojan horse,” which carries the pointer to the counter without affecting the code of the algorithm.

```

template<class Iter>
bool break_condition (const Iter&) { ... }

template<class ONodeIt, class OAdjIt>
void dummy_algorithm(ONodeIt& it, OAdjIt& it2) {
    while (it.valid()) {
        for (it2.update(it); it2.valid() && !break_condition(it2); ++it2)
            ++it;
    }
}

int write_count(graph& G) {
    typedef DummyObserver<NodeIt>           DummyObs;
    typedef SimpleCountObserver<AdjIt,DummyObs> CountObs;
    typedef ObserverNodeIt<DummyObs,NodeIt>  ONodeIt;
    typedef ObserverAdjIt<CountObs,AdjIt>    OAdjIt;

    DummyObs observer;
    ONodeIt  it(observer,NodeIt(G));
    CountObs observer2(observer);
    OAdjIt  it2(observer2,AdjIt(G));
    dummy_algorithm(it,it2);
    return it2.get_observer().counter();
}

```

14.12 STL Iterator Wrapper (*STLNodeIt*)

1. Definition

An instance *it* of class *STLNodeIt*< *DataAccessor*, *Iter* > is a STL iterator wrapper for node iterators (e.g. *NodeIt*, *FilterNodeIt*<*pred*,*NodeIt*>). It adds all type tags and methods that are necessary for STL conformance; see the standard draft working paper for details. The type tag *value_type* is equal to `typename DataAccessor::value_type` and the return value of `operator*`.

Class *STLEdgeIt* and *STLAdjIt* are defined analogously, i.e. can be used for edge iterators or adjacency iterators, respectively.

Precondition: The template parameter *Iter* must be a node iterator. *DataAccessor* must be a data accessor.

Note: There are specialized versions of STL wrapper iterator classes for each kind of iterator that return different LEDA graph objects.

class name	operator*() returns
NodeIt_n	node
EdgeIt_e	edge
AdjIt_n	node
AdjIt_e	edge
OutAdjIt_n	node
OutAdjIt_e	edge
InAdjIt_n	node
InAdjIt_e	edge

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
STLNodeIt< DataAccessor, Iter > it(DataAccessor da, const Iter& base_it);
```

introduces a variable *it* of this class bound to *da* and *base_it*.

3. Operations

```
STLNodeIt<DataAccessor, Iter>& it = typename DataAccessor::value_type i
```

assigns the value *i*, i.e. *set(DA, it, i)* will be invoked where *DA* is the associated data accessor and *it* the associated iterator.

```
bool it == const STLNodeIt<DataAccessor, Iter>& it2
```

returns **true** if the associated values of *it* and *it2* are equal, i.e. *get(DA, cit) == get(DA, cit2)* is true where *cit* is the associated iterator of *it* and *cit2* is the associated iterator of *it2* and *DA* is the associated data accessor.

```
bool it != const STLNodeIt<DataAccessor, Iter>& it2
```

returns **false** if the associated value equals the one of the given iterator.

```
STLNodeIt<DataAccessor, Iter>& it.begin()
```

resets the iterator to the beginning of the sequence.

```
STLNodeIt<DataAccessor, Iter>& it.last()
```

resets the iterator to the ending of the sequence.

```
STLNodeIt<DataAccessor, Iter>& it.end()
```

makes the iterators invalid, i.e. past-the-end-value.

typename DataAccessor::value_type& **it*

returns a reference to the associated value, which originally comes from data accessor *da*. If the associated iterator *it* is not valid, a dummy value reference is returned and should not be used.

Precondition: *access(DA, it)* returns a non constant reference to the data associated to *it* in *DA*. This functions is defined for all implemented data accessors (e.g. *node_array_da*, *edge_array_da*).

14.13 Node Array Data Accessor (*node_array_da*)

1. Definition

An instance *da* of class *node_array_da*<*T*> is instantiated with a LEDA *node_array*<*T*>.

The data in the node array can be accessed by the functions *get(da, it)* and *set(da, it, value)* that take as parameters an instance of *node_array_da*<*T*> and an iterator, see below.

node_array_da<*T*>::*value_type* is a type and equals *T*.

For *node_map*<*T*> there is the variant *node_map_da*<*T*> which is defined completely analogous to *node_array_da*<*T*>. Classes *edge_array_da*<*T*> and *edge_map_da*<*T*> are defined analogously, as well.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
node_array_da<T> da;
```

introduces a variable *da* of this class that is not bound.

```
node_array_da<T> da(leda::node_array<T>& na);
```

introduces a variable *da* of this class bound to *na*.

3. Operations

```
T get(const node_array_da<T>& da, const Iter& it)
```

returns the associated value of *it* for this accessor.

```
void set(node_array_da<T>& da, const Iter& it, T val)
```

sets the associated value of *it* for this accessor to the given value.

4. Implementation

Constant Overhead.

5. Example

We count the number of 'red nodes' in a parameterized graph G.

```
int count_red(graph G, node_array<color> COL) {
    node_array_da<color> Color(COL);
    int counter=0;
    NodeIt it(G);
    while (it.valid()) {
        if (get(Color,it)==red) counter++;
        it++; }
    return counter;
}
```

Suppose we want to make this 'algorithm' flexible in the representation of colors. Then we could write this version:

```
template<class DA>
int count_red_t(graph G, DA Color) {
    int counter=0;
    NodeIt it(G);
    while (it.valid()) {
        if (get(Color,it)==red) counter++;
        it++; }
    return counter;
}
```

With the templated version it is easily to customize it to match the interface of the version:

```
int count_red(graph G, node_array<color> COL) {
    node_array_da<color> Color(COL);
    return count_red_t(G,Color); }
```

14.14 Constant Accessors (*constant_da*)

1. Definition

An instance *ca* of class *constant_da*<*T*> is bound to a specific value of type *T*, and the function *get(ca, it)* simply returns this value for each iterator.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
constant_da<T> ca(T t);
```

introduces a variable *ca* of this class bound to the given value *t*.

3. Operations

```
T get(const constant_da<T>& ca, const Iter& it)
```

returns the value to which *ca* is bound.

4. Example

With the template function of sect. 14.13 we can write a function that counts the number of nodes in a graph:

```
int count_all(graph G) {
    constant_da<color> Color(red);
    return count_red_t(G,Color); }
```

14.15 Node Member Accessors (*node_member_da*)

1. Definition

An instance *da* of class *node_member_da*<*Str, T*> manages the access to a node parameter that is organized as a member of a struct type, which is the first template argument of a parameterized graph *GRAPH*<*Str, ?*>. The parameter is of type *T* and the struct of type *Str*.

Classes *edge_member_da*<*Str, T*> is defined completely analogously.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
node_member_da<Str,T> da;
```

introduces a variable *da* of this class that is not bound.

```
node_member_da<Str,T> da(Ptr ptr);
```

introduces a variable *da* of this class, which is bound to *ptr*.

3. Operations

```
T          get(const node_member_da<Str,T>& ma, const Iter& it)
```

returns the associated value of *it* for this accessor.

```
void       set(node_member_da<Str,T>& ma, const Iter& it, T val)
```

sets the associated value of *it* for this accessor to the given value.

4. Implementation

Constant Overhead.

The instance *da* accesses its parameter through a pointer to member of type `Ptr`, which is defined for example by `typedef T Str::*Ptr`.

5. Example

We have a parameterized graph *G* where the node information type is the following struct type `Str`:

```
struct Str {
    int x;
    color col; };
```

We want to count the number of red nodes. Since we have the template function of sect. 14.13 we can easily use it to do the computation:

```
int count_red(GRAPH<Str,double> G) {
    node_member_da<Str,color> Color(&Str::col);
    return count_red_t(G,Color); }
```

14.16 Node Attribute Accessors (`node_attribute_da`)

1. Definition

An instance *da* of class `node_attribute_da<T>` manages the access to a node parameter with type *T* of a parameterized graph `GRAPH<T, ?>`.

Classes `edge_attribute_da<T>` is defined completely analogously.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
node_attribute_da<T> da;
```

introduces a variable *da* of this class.

3. Operations

```
T get(const node_attribute_da<T>& ma, const Iter& it)
```

returns the associated value of *it* for this accessor.

```
void set(node_attribute_da<T>& ma, const Iter& it, T val)
```

sets the associated value of *it* for this accessor to the given value.

4. Implementation

Constant Overhead.

5. Example

Given a parameterized graph *G* with nodes associated with colours, we want to count the number of red nodes. Since we have the template function of sect. 14.13 we can easily use it to do the computation:

```
int count_red(GRAPH<color,double> G) {
    node_attribute_da<color> Color;
    return count_red_t(G,Color); }
```

14.17 Breadth First Search (flexible) (GIT_BFS)

1. Definition

An instance *algorithm* of class *GIT_BFS*< *OutAdjIt*, *QueueType*, *Mark* > is an implementation of an algorithm that traverses a graph in a breadth first order. The queue used for the search must be provided by the caller and contains the source(s) of the search.

- If the queue is only modified by appending the iterator representing the source node onto the queue, a normal breadth first search beginning at the node of the graph is performed.
- It is possible to initialize the queue with several iterators that represent different roots of breadth first trees.
- By modifying the queue while running the algorithm the behaviour of the algorithm can be changed.
- After the algorithm performed a breadth first search, one may append another iterator onto the queue to restart the algorithm.

Iterator version: There is an iterator version of this algorithm: *BFS_It*. Usage is similar to that of node iterators without the ability to go backward in the sequence.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
GIT_BFS< OutAdjIt, QueueType, Mark >
```

```
    algorithm(const QueueType& q, Mark& ma);
```

creates an instance *algorithm* of this class bound to the Queue *q* and data accessor *ma*.

Preconditions:

- *QueueType* is a queue parameterized with items of type *OutAdjIt*.
- *q* contains the sources of the traversal (for each source node an adjacency iterator referring to it) and
- *ma* is a data accessor that provides read and write access to a boolean value for each node (accessed through iterators). This value is assumed to be freely usable by *algorithm*.

With this iterator you can easily iterate through a graph in breadth first fashion :

```
graph G;
BFS_It it(G);
while (it.valid()) {
    // do something reasonable with 'it.get_node()'
    ++it;
}
```

5. Implementation

Each operation requires constant time. Therefore, a normal breadth-first search needs $\mathcal{O}(m + n)$ time.

14.18 Depth First Search (flexible) (GIT_DFS)

1. Definition

An instance *algorithm* of class *GIT_DFS*< *OutAdjIt*, *Stacktype*, *Mark* > is an implementation of an algorithm that traverses a graph in a depth first order. The stack used for the search must be provided by the caller and contains the source(s) of the search.

- If the stack is only modified by pushing the iterator representing the source node onto the stack, a normal depth first search beginning at the node of the graph is performed.
- It is possible to initialize the stack with several iterators that represent different roots of depth first trees.
- By modifying the stack while running the algorithm the behaviour of the algorithm can be changed.
- After the algorithm performed a depth first search, one may push another iterator onto the stack to restart the algorithm.

A next step may return a state which describes the last action. There are the following three possibilities:

1. `dfs_shrink`: an adjacency iterator was popped from the stack, i.e. the treewalk returns in root-direction
2. `dfs_leaf`: same as `dfs_shrink`, but a leaf occurred

3. `dfs_grow_depth`: a new adjacency iterator was appended to the stack because it was detected as not seen before, i.e. the treewalk goes in depth-direction
4. `dfs_grow_breadth`: the former current adjacency iterator was replaced by the successor iterator, i.e. the treewalk goes in breadth-direction

Iterator version: There is an iterator version of this algorithm: `DFS_It`. Usage is similar to that of node iterators without the ability to go backward in the sequence.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
GIT_DFS< OutAdjIt, Stacktype, Mark >
```

```
    algorithm(const Stacktype& st, Mark& ma);
```

creates an instance *algorithm* of this class bound to the stack *st* and data accessor *ma*.

Preconditions:

- `Stacktype` is a stack parameterized with items of type `OutAdjIt`.
- *st* contains the sources of the traversal (for each source node an adjacency iterator referring to it) and
- *ma* is a data accessor that provides read and write access to a boolean value for each node (accessed through iterators). This value is assumed to be freely usable by *algorithm*.

```
GIT_DFS< OutAdjIt, Stacktype, Mark >
```

```
    algorithm(const Stacktype& st, Mark& ma, const OutAdjIt& ai);
```

creates an instance *algorithm* of this class bound to the stack *st*, data accessor *ma* and the adjacency iterator *ai* representing the source node of the depth first traversal.

3. Operations

```
void          algorithm.next_unseen()
```

Performs one iteration of the core loop of the algorithm for one unseen node of the graph.

```
dfs_return    algorithm.next()
```

Performs one iteration of the core loop of the algorithm.

```
OutAdjIt     algorithm.current() returns the "current" iterator.
```

void `algorithm.finish_algo()` executes the algorithm until `finished()` is true, i.e. exactly if the stack is empty.

bool `algorithm.finished()` returns `true` if the internal stack is empty.

void `algorithm.init(OutAdjIt s)` initializes the internal stack with *s*.

Stacktype& `algorithm.get_stack()` gives direct access to internal stack.

4. Implementation

Each operation requires constant time. Therefore, a normal depth-first search needs $\mathcal{O}(m + n)$ time.

14.19 Topological Sort (flexible) (GIT_TOPOSORT)

1. Definition

An instance *algorithm* of class `GIT_TOPOSORT< OutAdjIt, Indeg, QueueType >` is an implementation of an algorithm that iterates over all nodes in some topological order, if the underlying graph is acyclic. An object of this class maintains an *internal queue*, which contains all nodes (in form of adjacency iterators where the current node is equal to the fixed node) that are not yet passed, but all its predecessors have been passed.

Iterator version: There is an iterator version of this algorithm: `TOPO_It`. Usage is similar to that of node iterators without the ability to go backward in the sequence and only a graph is allowed at creation time. Additionally there is `TOPO_rev_It` which traverses the graph in reversed topological order.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
GIT_TOPOSORT< OutAdjIt, Indeg, QueueType >  
algorithm(Indeg& indegree);
```

creates an instance *algorithm* of this class bound to *indeg*. The internal queue of adjacency iterators is empty.

Preconditions:

- `Indeg` is a data accessor that must provide both read and write access

- *indegree* stores for every node that corresponds to any iterator the number of incoming edges (has to be computed before)
- *QueueType* is a queue parameterized with elements of type *OutAdjIt*

The underlying graph need not be acyclic. Whether or not it is acyclic can be tested after execution of the algorithm (function `cycle_found()`).

3. Operations

<i>void</i>	<i>algorithm.next()</i>	Performs one iteration of the core loop of the algorithm. More specifically, the first element of <code>get_queue()</code> is removed from the queue, and every immediate successor <i>n</i> of this node for which currently holds <code>get(indeg,n)==0</code> is inserted in <code>get_queue()</code> .
<i>void</i>	<i>algorithm.finish_algo()</i>	executes the algorithm until <code>finished()</code> is true, i.e. exactly if the queue is empty.
<i>bool</i>	<i>algorithm.finished()</i>	returns <code>true</code> if the internal queue is empty.
<i>OutAdjIt</i>	<i>algorithm.current()</i>	returns the current adjacency iterator.
<i>QueueType&</i>	<i>algorithm.get_queue()</i>	gives direct access to internal queue.
<i>bool</i>	<i>algorithm.cycle_found()</i>	returns <code>true</code> if a cycle was found.
<i>void</i>	<i>algorithm.reset_acyclic()</i>	resets the internal flag that a cycle was found.

4. Implementation

The asymptotic complexity is $\mathcal{O}(m + n)$, where *m* is the number of edges and *n* the number of nodes.

5. Example

This algorithm performs a normal topological sort if the queue is initialized by the set of all nodes with indegree zero:

Definition of *algorithm*, where *indeg* is a data accessor that provides full data access to the number of incoming edges for each node:

```
GIT_TOPOSORT<OutAdjIt,Indeg,QueueType<Nodehandle> > algorithm(indeg);
```

Initialization of `get_queue()` with all nodes of type `OutAdjIt::nodetype` that have zero indegree, i.e. `get(indeg,it)==indeg.value_null`.

```
while ( !algorithm.finished() ) {
    // do something reasonable with algo.current()
    algo.next();
}
```

The source code of function `toposort_count()` is implemented according to this pattern and may serve as a concrete example.

14.20 Strongly Connected Components (flexible) (GIT_SCC)

1. Definition

An instance *algorithm* of class `GIT_SCC< Out, In, It, OutSt, InSt, NSt, Mark >` is an implementation of an algorithm that computes the strongly connected components.

Iterator version: There is an iterator version of this algorithm: `SCC_It`. Usage is similar to that of node iterators without the ability to go backward in the sequence and only a graph is allowed at creation time. Method `compnumb()` returns the component number of the current node.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
GIT_SCC< Out, In, It, OutSt, InSt, NSt, Mark >
```

```
    algorithm(OutSt ost, InSt ist, Mark ma, Out oai, const It& it, In iai);
```

creates an instance *algorithm* of this class bound to the stack *st* and data accessor *ma*.

Preconditions:

- `Out` is an adjacency iterator that iterates over the outgoing edges of a fixed vertex
- `In` is an adjacency iterator that iterates over the incoming edges of a fixed vertex
- `OutSt` is stack parameterized with items of type `Out`
- `InSt` is stack parameterized with items of type `In`

14.21 Dijkstra(flexible) (GIT_DIJKSTRA)

1. Definition

An instance *algorithm* of this class is an implementation of Dijkstra that can be flexibly initialized, stopped after each iteration of the core loop, and continued, time and again.

Iterator version: There is an iterator version of this algorithm: `DIJKSTRA_It`. Usage is more complex and is documented in the graphiterator leda extension package.

```
#include < LEDA/graph/graph_iterator.h >
```

2. Creation

```
GIT_DIJKSTRA< OutAdjIt, Length, Distance, PriorityQueue, QueueItem >
    algorithm(const Length& l, Distance& d, const QueueItem& qi);
```

creates an instance *algorithm* of this class.

The length and distance data accessors are initialized by the parameter list. The set of sources is empty. `Length` is a read only data accessor that gives access to the length of edges and `Distance` is a read/write data accessor that stores the distance of the nodes. `PriorityQueue` is a Queue parameterized with element of type `OutAdjIt` and `QueueItem` is a data accessor gives access to elements of type `PriorityQueue::pq_item`.

Precondition: All edge lengths are initialized by values that are large enough to be taken as infinity.

Remark: This precondition is not necessary for the algorithm to have a defined behavior. In fact, it may even make sense to break this precondition deliberately. For example, if the distances have been computed before and shall only be updated after inserting new edges, it makes perfect sense to start the algorithm with these distances.

For a completely new computation, the node distances of all nodes are initialized to infinity(i.e. `distance.value_max`).

3. Operations

```
PriorityQueue& algorithm.get_queue()
```

gives direct access to internal priority queue.

```
void algorithm.init(OutAdjIt s)
```

s is added to the set of sources.

```
bool algorithm.finished()
```

is true iff the algorithm is finished, i.e. the priority queue is empty.

```
OutAdjIt algorithm.current()
```

returns the current adjacency iterator.

<i>OutAdjIt</i>	<i>algorithm.curr_adj()</i>	returns the an adjacency iterator that is currently adjacent to <i>current()</i> .
<i>bool</i>	<i>algorithm.is_pred()</i>	returns true if the current iterator satisfies the dijkstra condition. Can be used to compute the predecessors.
<i>void</i>	<i>algorithm.next()</i>	performs one iteration of the core loop of the algorithm.
<i>void</i>	<i>algorithm.finish_algo()</i>	executes the algorithm until <i>finished()</i> is true, i.e. exactly if the priority queue is empty.

4. Example

Class GIT_DIJKSTRA may be used in a deeper layer in a hierarchy of classes and functions. For example, you may write a function which computes shortest path distances with given iterators and data accessors:

```
template<class OutAdjIt, class Length, class Distance,
        class PriorityQueue, class QueueItem>
void GIT_dijkstra_core(OutAdjIt s, Length& length, Distance& distance,
    PriorityQueue& pq, QueueItem& qi) {
    GIT_DIJKSTRA<OutAdjIt,Length,Distance,PriorityQueue,QueueItem>
        internal_dijk(length,distance,qi);
    internal_dijk.get_queue()=pq;
    set(distance,s,distance.value_null);
    if (s.valid()) {
        internal_dijk.init(s);
        internal_dijk.finish_algo();
    }
}
```

In another layer, you would instantiate these iterators and data accessors for a graph and invoke this function.

5. Implementation

The asymptotic complexity is $\mathcal{O}(m + n \cdot T(n))$, where $T(n)$ is the (possibly amortized) complexity of a single queue update.

For the priority queues described in Chapter 9.1, it is $T(n) = \mathcal{O}(\log n)$.

Chapter 15

Basic Data Types for Two-Dimensional Geometry

LEDA provides a collection of simple data types for computational geometry, such as points, vectors, directions, hyperplanes, segments, rays, lines, affine transformations, circles, polygons, and operations connecting these types.

The computational geometry kernel has evolved over time. The first kernel (types *point*, *line*, ...) was restricted to two-dimensional geometry and used floating point arithmetic as the underlying arithmetic. We found it very difficult to implement reliable geometric algorithms based on this kernel. See the chapter on computational geometry of [64] for some examples of the danger of floating point arithmetic in geometric computations. Starting with version 3.2 we therefore also provided a kernel based on exact rational arithmetic (types *rat_point*, *rat_segment* ...). (This kernel is still restricted to two dimensions.) From version 4.5 on we offer a two-dimensional kernel based on the type *real*, which also guarantees exact results. The corresponding data types are named *real_point*, *real_segment*, ...

All two-dimensional object types defined in this section support the following operations:

Equality and Identity Tests

<i>bool</i>	<code>identical(object p, object q)</code>	Test for identity.
<i>bool</i>	<code>p == q</code>	Test for equality.
<i>bool</i>	<code>p != q</code>	Test for inequality.

I/O Operators

<i>ostream&</i>	<code>ostream& O << object x</code>	writes the object <i>x</i> to output stream <i>O</i> .
<i>istream&</i>	<code>istream& I >> object& x</code>	reads an object from input stream <i>I</i> into variable <i>x</i> .

15.1 Points (`point`)

1. Definition

An instance of the data type *point* is a point in the two-dimensional plane \mathbb{R}^2 . We use (x, y) to denote a point with first (or x-) coordinate x and second (or y-) coordinate y .

```
#include < LEDA/geo/point.h >
```

2. Types

point::*coord_type* the coordinate type (*double*).

point::*point_type* the point type (*point*).

3. Creation

point *p*; introduces a variable *p* of type *point* initialized to the point $(0, 0)$.

point *p*(*double* *x*, *double* *y*);
 introduces a variable *p* of type *point* initialized to the point (x, y) .

point *p*(*vector* *v*); introduces a variable *p* of type *point* initialized to the point $(v[0], v[1])$.
Precondition: : *v.dim*() = 2.

point *p*(*const point*& *p*, *int* *prec*);
 introduces a variable *p* of type *point* initialized to the point with coordinates $(\lfloor P * x \rfloor / P, \lfloor P * y \rfloor / P)$, where $p = (x, y)$ and $P = 2^{prec}$. If *prec* is non-positive, the new point has coordinates x and y .

4. Operations

double *p.xcoord*() returns the first coordinate of *p*.

double *p.ycoord*() returns the second coordinate of *p*.

vector *p.to_vector*() returns the vector \vec{xy} .

int *p.orientation*(*const point*& *q*, *const point*& *r*)
 returns *orientation*(*p, q, r*) (see below).

double *p.area*(*const point*& *q*, *const point*& *r*)
 returns *area*(*p, q, r*) (see below).

point `p.reflect(const point& q, const point& r)`
 returns p reflected across the straight line passing through q and r .

point `p.reflect(const point& q)`
 returns p reflected across point q .

vector `p - const point& q` returns the difference vector of the coordinates.

Non-Member Functions

int `cmp_distances(const point& p1, const point& p2, const point& p3, const point& p4)`
 compares the distances $(p1, p2)$ and $(p3, p4)$. Returns +1 (-1) if distance $(p1, p2)$ is larger (smaller) than distance $(p3, p4)$, otherwise 0.

point `center(const point& a, const point& b)`
 returns the center of a and b , i.e. $a + \vec{ab}/2$.

point `midpoint(const point& a, const point& b)`
 returns the center of a and b .

int `orientation(const point& a, const point& b, const point& c)`
 computes the orientation of points a , b , and c as the sign of the determinant

$$\begin{vmatrix} a_x & a_y & 1 \\ b_x & b_y & 1 \\ c_x & c_y & 1 \end{vmatrix}$$

i.e., it returns +1 if point c lies left of the directed line through a and b , 0 if a, b , and c are collinear, and -1 otherwise.

int `cmp_signed_dist(const point& a, const point& b, const point& c, const point& d)`
 compares (signed) distances of c and d to the straight line passing through a and b (directed from a to b). Returns +1 (-1) if c has larger (smaller) distance than d and 0 if distances are equal.

double `area(const point& a, const point& b, const point& c)`
 computes the signed area of the triangle determined by a, b, c , positive if $orientation(a, b, c) > 0$ and negative otherwise.

- bool* `collinear(const point& a, const point& b, const point& c)`
returns *true* if points a , b , c are collinear, i.e., $orientation(a, b, c) = 0$, and *false* otherwise.
- bool* `right_turn(const point& a, const point& b, const point& c)`
returns *true* if points a , b , c form a right turn, i.e., $orientation(a, b, c) < 0$, and *false* otherwise.
- bool* `left_turn(const point& a, const point& b, const point& c)`
returns *true* if points a , b , c form a left turn, i.e., $orientation(a, b, c) > 0$, and *false* otherwise.
- int* `side_of_halfspace(const point& a, const point& b, const point& c)`
returns the sign of the scalar product $(b - a) \cdot (c - a)$. If $b \neq a$ this amounts to: Let h be the open halfspace orthogonal to the vector $b - a$, containing b , and having a in its boundary. Returns $+1$ if c is contained in h , returns 0 if c lies on the boundary of h , and returns -1 if c is contained in the interior of the complement of h .
- int* `side_of_circle(const point& a, const point& b, const point& c, const point& d)`
returns $+1$ if point d lies left of the directed circle through points a , b , and c , 0 if $a, b, c, \text{ and } d$ are cocircular, and -1 otherwise.
- bool* `inside_circle(const point& a, const point& b, const point& c, const point& d)`
returns *true* if point d lies in the interior of the circle through points a , b , and c , and *false* otherwise.
- bool* `outside_circle(const point& a, const point& b, const point& c, const point& d)`
returns *true* if point d lies outside of the circle through points a , b , and c , and *false* otherwise.
- bool* `on_circle(const point& a, const point& b, const point& c, const point& d)`
returns *true* if points a , b , c , and d are cocircular.
- bool* `cocircular(const point& a, const point& b, const point& c, const point& d)`
returns *true* if points a , b , c , and d are cocircular.
- int* `compare_by_angle(const point& a, const point& b, const point& c,
const point& d)`
compares vectors $b - a$ and $d - c$ by angle (more efficient than calling `compare_by_angle(b - a, d - c)` on vectors).
- bool* `affinely_independent(const array<point>& A)`
decides whether the points in A are affinely independent.

- bool* `contained_in_simplex(const array<point>& A, const point& p)`
determines whether p is contained in the simplex spanned by the points in A . A may consist of up to 3 points.
Precondition: The points in A are affinely independent.
- bool* `contained_in_affine_hull(const array<point>& A, const point& p)`
determines whether p is contained in the affine hull of the points in A .

15.2 Segments (segment)

1. Definition

An instance s of the data type *segment* is a directed straight line segment in the two-dimensional plane, i.e., a straight line segment $[p, q]$ connecting two points $p, q \in \mathbb{R}^2$. p is called the *source* or start point and q is called the *target* or end point of s . The length of s is the Euclidean distance between p and q . If $p = q$ s is called empty. We use $line(s)$ to denote a straight line containing s . The angle between a right oriented horizontal ray and s is called the direction of s .

```
#include < LEDA/geo/segment.h >
```

2. Types

segment::coord_type the coordinate type (*double*).

segment::point_type the point type (*point*).

3. Creation

```
segment  $s(const\ point\&\ p, const\ point\&\ q);$ 
```

introduces a variable s of type *segment*. s is initialized to the segment $[p, q]$.

```
segment  $s(const\ point\&\ p, const\ vector\&\ v);$ 
```

introduces a variable s of type *segment*. s is initialized to the segment $[p, p + v]$.

Precondition: $v.dim() = 2$.

```
segment  $s(double\ x1, double\ y1, double\ x2, double\ y2);$ 
```

introduces a variable s of type *segment*. s is initialized to the segment $[(x_1, y_1), (x_2, y_2)]$.

```
segment  $s(const\ point\&\ p, double\ alpha, double\ length);$ 
```

introduces a variable s of type *segment*. s is initialized to the segment with start point p , direction $alpha$, and length $length$.

```
segment  $s;$ 
```

introduces a variable s of type *segment*. s is initialized to the empty segment.

```
segment  $s(const\ segment\&\ s1, int);$ 
```

introduces a variable s of type *segment*. s is initialized to a copy of s_1 .

4. Operations

<i>point</i>	<code>s.start()</code>	returns the source point of segment s .
<i>point</i>	<code>s.end()</code>	returns the target point of segment s .
<i>double</i>	<code>s.xcoord1()</code>	returns the x-coordinate of $s.source()$.
<i>double</i>	<code>s.xcoord2()</code>	returns the x-coordinate of $s.target()$.
<i>double</i>	<code>s.ycoord1()</code>	returns the y-coordinate of $s.source()$.
<i>double</i>	<code>s.ycoord2()</code>	returns the y-coordinate of $s.target()$.
<i>double</i>	<code>s.dx()</code>	returns the $xcoord2 - xcoord1$.
<i>double</i>	<code>s.dy()</code>	returns the $ycoord2 - ycoord1$.
<i>double</i>	<code>s.slope()</code>	returns the slope of s . <i>Precondition:</i> s is not vertical.
<i>double</i>	<code>s.sqr_length()</code>	returns the square of the length of s .
<i>double</i>	<code>s.length()</code>	returns the length of s .
<i>vector</i>	<code>s.to_vector()</code>	returns the vector $s.target() - s.source()$.
<i>double</i>	<code>s.direction()</code>	returns the direction of s as an angle in the interval $[0, 2\pi)$.
<i>double</i>	<code>s.angle()</code>	returns $s.direction()$.
<i>double</i>	<code>s.angle(const segment& t)</code>	returns the angle between s and t , i.e., $t.direction() - s.direction()$.
<i>bool</i>	<code>s.is_trivial()</code>	returns true if s is trivial.
<i>bool</i>	<code>s.is_vertical()</code>	returns true iff s is vertical.
<i>bool</i>	<code>s.is_horizontal()</code>	returns true iff s is horizontal.
<i>int</i>	<code>s.orientation(const point& p)</code>	computes $orientation(s.source(), s.target(), p)$ (see below).
<i>double</i>	<code>s.x_proj(double y)</code>	returns $p.xcoord()$, where $p \in line(s)$ with $p.ycoord() = y$. <i>Precondition:</i> s is not horizontal.
<i>double</i>	<code>s.y_proj(double x)</code>	returns $p.ycoord()$, where $p \in line(s)$ with $p.xcoord() = x$. <i>Precondition:</i> s is not vertical.
<i>double</i>	<code>s.y_abs()</code>	returns the y-abscissa of $line(s)$, i.e., $s.y_proj(0)$. <i>Precondition:</i> s is not vertical.

segment `s.rotate90(const point& q, int i = 1)`
 returns *s* rotated about *q* by an angle of $i \times 90$ degrees.
 If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

segment `s.rotate90(int i = 1)`
 returns `s.rotate90(s.source(),i)`.

segment `s.reflect(const point& p, const point& q)`
 returns *s* reflected across the straight line passing through *p* and *q*.

segment `s.reflect(const point& p)`
 returns *s* reflected across point *p*.

segment `s.reverse()` returns *s* reversed.

Non-Member Functions

int `orientation(const segment& s, const point& p)`
 computes `orientation(s.source(), s.target(), p)`.

int `cmp_slopes(const segment& s1, const segment& s2)`
 returns `compare(slope(s1), slope(s2))`.

int `cmp_segments_at_xcoord(const segment& s1, const segment& s2, const point& p)`
 compares points $l_1 \cap v$ and $l_2 \cap v$ where l_i is the line underlying segment s_i and v is the vertical straight line passing through point *p*.

bool `parallel(const segment& s1, const segment& s2)`
 returns true if s_1 and s_2 are parallel and false otherwise.

15.3 Straight Rays (ray)

1. Definition

An instance r of the data type *ray* is a directed straight ray in the two-dimensional plane. The angle between a right oriented horizontal ray and r is called the direction of r .

```
#include < LEDA/geo/ray.h >
```

2. Types

ray::*coord_type* the coordinate type (*double*).

ray::*point_type* the point type (*point*).

3. Creation

```
ray r(const point& p, const point& q);
```

introduces a variable r of type *ray*. r is initialized to the ray starting at point p and passing through point q .

```
ray r(const segment& s);
```

introduces a variable r of type *ray*. r is initialized to $\text{ray}(s.\text{source}(), s.\text{target}())$.

```
ray r(const point& p, const vector& v);
```

introduces a variable r of type *ray*. r is initialized to $\text{ray}(p, p+v)$.

```
ray r(const point& p, double alpha);
```

introduces a variable r of type *ray*. r is initialized to the ray starting at point p with direction α .

```
ray r;
```

introduces a variable r of type *ray*. r is initialized to the ray starting at the origin with direction 0.

```
ray r(const ray& r1, int);
```

introduces a variable r of type *ray*. r is initialized to a copy of r_1 . The second argument is for compatibility with *rat_ray*.

4. Operations

point $r.\text{source}()$ returns the source of r .

point $r.\text{point1}()$ returns the source of r .

point $r.\text{point2}()$ returns a point on r different from $r.\text{source}()$.

<i>double</i>	<i>r.direction()</i>	returns the direction of <i>r</i> .
<i>double</i>	<i>r.angle(const ray& s)</i>	returns the angle between <i>r</i> and <i>s</i> , i.e., <i>s.direction() - r.direction()</i> .
<i>bool</i>	<i>r.is_vertical()</i>	returns true iff <i>r</i> is vertical.
<i>bool</i>	<i>r.is_horizontal()</i>	returns true iff <i>r</i> is horizontal.
<i>double</i>	<i>r.slope()</i>	returns the slope of the straight line underlying <i>r</i> . <i>Precondition: r</i> is not vertical.
<i>bool</i>	<i>r.intersection(const ray& s, point& inter)</i>	if <i>r</i> and <i>s</i> intersect in a single point this point is assigned to <i>inter</i> and the result is <i>true</i> , otherwise the result is <i>false</i> .
<i>bool</i>	<i>r.intersection(const segment& s, point& inter)</i>	if <i>r</i> and <i>s</i> intersect in a single point this point is assigned to <i>inter</i> and the result is <i>true</i> , otherwise the result is <i>false</i> .
<i>bool</i>	<i>r.intersection(const segment& s)</i>	test if <i>r</i> and <i>s</i> intersect.
<i>ray</i>	<i>r.translate_by_angle(double a, double d)</i>	returns <i>r</i> translated in direction <i>a</i> by distance <i>d</i> .
<i>ray</i>	<i>r.translate(double dx, double dy)</i>	returns <i>r</i> translated by vector (dx, dy) .
<i>ray</i>	<i>r.translate(const vector& v)</i>	returns <i>r</i> translated by vector <i>v</i> <i>Precondition: v.dim() = 2.</i>
<i>ray</i>	<i>r + const vector& v</i>	returns <i>r</i> translated by vector <i>v</i> .
<i>ray</i>	<i>r - const vector& v</i>	returns <i>r</i> translated by vector $-v$.
<i>ray</i>	<i>r.rotate(const point& q, double a)</i>	returns <i>r</i> rotated about point <i>q</i> by angle <i>a</i> .
<i>ray</i>	<i>r.rotate(double a)</i>	returns <i>r.rotate(point(0,0), a)</i> .
<i>ray</i>	<i>r.rotate90(const point& q, int i = 1)</i>	returns <i>r</i> rotated about <i>q</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

<i>ray</i>	<i>r</i> .reflect(<i>const point& p</i> , <i>const point& q</i>)	returns <i>r</i> reflected across the straight line passing through <i>p</i> and <i>q</i> .
<i>ray</i>	<i>r</i> .reflect(<i>const point& p</i>)	returns <i>r</i> reflected across point <i>p</i> .
<i>ray</i>	<i>r</i> .reverse()	returns <i>r</i> reversed.
<i>bool</i>	<i>r</i> .contains(<i>const point& </i>)	decides whether <i>r</i> contains <i>p</i> .
<i>bool</i>	<i>r</i> .contains(<i>const segment& </i>)	decides whether <i>r</i> contains <i>s</i> .

Non-Member Functions

<i>int</i>	orientation(<i>const ray& r</i> , <i>const point& p</i>)	computes orientation(<i>a</i> , <i>b</i> , <i>p</i>), where <i>a</i> ≠ <i>b</i> and <i>a</i> and <i>b</i> appear in this order on ray <i>r</i> .
<i>int</i>	cmp_slopes(<i>const ray& r1</i> , <i>const ray& r2</i>)	returns compare(slope(<i>r</i> ₁), slope(<i>r</i> ₂)) where slope(<i>r</i> _{<i>i</i>}) denotes the slope of the straight line underlying <i>r</i> _{<i>i</i>} .

15.4 Straight Lines (line)

1. Definition

An instance l of the data type *line* is a directed straight line in the two-dimensional plane. The angle between a right oriented horizontal line and l is called the direction of l .

```
#include < LEDA/geo/line.h >
```

2. Types

line::coord_type the coordinate type (*double*).

line::point_type the point type (*point*).

3. Creation

```
line l(const point& p, const point& q);
```

introduces a variable l of type *line*. l is initialized to the line passing through points p and q directed from p to q .

```
line l(const segment& s);
```

introduces a variable l of type *line*. l is initialized to the line supporting segment s .

```
line l(const ray& r);
```

introduces a variable l of type *line*. l is initialized to the line supporting ray r .

```
line l(const point& p, const vector& v);
```

introduces a variable l of type *line*. l is initialized to the line passing through points p and $p + v$.

```
line l(const point& p, double alpha);
```

introduces a variable l of type *line*. l is initialized to the line passing through point p with direction $alpha$.

```
line l;
```

introduces a variable l of type *line*. l is initialized to the line passing through the origin with direction 0.

4. Operations

point $l.point1()$ returns a point on l .

point $l.point2()$ returns a second point on l .

segment $l.seg()$ returns a segment on l .

double $l.angle(const line& g)$ returns the angle between l and g , i.e., $g.direction() - l.direction()$.

<i>double</i>	<i>l.direction()</i>	returns the direction of <i>l</i> .
<i>double</i>	<i>l.angle()</i>	returns <i>l.direction()</i> .
<i>bool</i>	<i>l.is_vertical()</i>	returns true iff <i>l</i> is vertical.
<i>bool</i>	<i>l.is_horizontal()</i>	returns true iff <i>l</i> is horizontal.
<i>double</i>	<i>l.sqr_dist(const point& q)</i>	returns the square of the distance between <i>l</i> and <i>q</i> .
<i>double</i>	<i>l.distance(const point& q)</i>	returns the distance between <i>l</i> and <i>q</i> .
<i>int</i>	<i>l.orientation(const point& p)</i>	returns <i>orientation(l.point1(), l.point2(), p)</i> .
<i>double</i>	<i>l.slope()</i>	returns the slope of <i>l</i> . <i>Precondition: l</i> is not vertical.
<i>double</i>	<i>l.y_proj(double x)</i>	returns <i>p.ycoord()</i> , where $p \in l$ with $p.xcoord() = x$. <i>Precondition: l</i> is not vertical.
<i>double</i>	<i>l.x_proj(double y)</i>	returns <i>p.xcoord()</i> , where $p \in l$ with $p.ycoord() = y$. <i>Precondition: l</i> is not horizontal.
<i>double</i>	<i>l.y_abs()</i>	returns the y- <i>abscissa</i> of <i>l</i> (<i>l.y_proj(0)</i>). <i>Precondition: l</i> is not vertical.
<i>bool</i>	<i>l.intersection(const line& g, point& p)</i>	if <i>l</i> and <i>g</i> intersect in a single point this point is assigned to <i>p</i> and the result is true, otherwise the result is false.
<i>bool</i>	<i>l.intersection(const segment& s, point& inter)</i>	if <i>l</i> and <i>s</i> intersect in a single point this point is assigned to <i>p</i> and the result is true, otherwise the result is false.
<i>bool</i>	<i>l.intersection(const segment& s)</i>	returns <i>true</i> , if <i>l</i> and <i>s</i> intersect, <i>false</i> otherwise.
<i>line</i>	<i>l.translate_by_angle(double a, double d)</i>	returns <i>l</i> translated in direction <i>a</i> by distance <i>d</i> .
<i>line</i>	<i>l.translate(double dx, double dy)</i>	returns <i>l</i> translated by vector (<i>dx</i> , <i>dy</i>).

<i>line</i>	<i>l.translate(const vector& v)</i>	returns <i>l</i> translated by vector <i>v</i> . <i>Precondition:</i> <i>v.dim() = 2</i> .
<i>line</i>	<i>l + const vector& v</i>	returns <i>l</i> translated by vector <i>v</i> .
<i>line</i>	<i>l - const vector& v</i>	returns <i>l</i> translated by vector $-v$.
<i>line</i>	<i>l.rotate(const point& q, double a)</i>	returns <i>l</i> rotated about point <i>q</i> by angle <i>a</i> .
<i>line</i>	<i>l.rotate(double a)</i>	returns <i>l.rotate(point(0,0), a)</i> .
<i>line</i>	<i>l.rotate90(const point& q, int i = 1)</i>	returns <i>l</i> rotated about <i>q</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
<i>line</i>	<i>l.reflect(const point& p, const point& q)</i>	returns <i>l</i> reflected across the straight line passing through <i>p</i> and <i>q</i> .
<i>line</i>	<i>l.reverse()</i>	returns <i>l</i> reversed.
<i>segment</i>	<i>l.perpendicular(const point& p)</i>	returns the segment perpendicular to <i>l</i> with source <i>p</i> . and target on <i>l</i> .
<i>point</i>	<i>l.dual()</i>	returns the point dual to <i>l</i> . <i>Precondition:</i> <i>l</i> is not vertical.
<i>int</i>	<i>l.side_of(const point& p)</i>	computes $\text{orientation}(a, b, p)$, where $a \neq b$ and <i>a</i> and <i>b</i> appear in this order on line <i>l</i> .
<i>bool</i>	<i>l.contains(const point& p)</i>	returns true if <i>p</i> lies on <i>l</i> .
<i>bool</i>	<i>l.clip(point p, point q, segment& s)</i>	clips <i>l</i> at the rectangle <i>R</i> defined by <i>p</i> and <i>q</i> . Returns true if the intersection of <i>R</i> and <i>l</i> is non-empty and returns false otherwise. If the intersection is non-empty the intersection is assigned to <i>s</i> ; It is guaranteed that the source node of <i>s</i> is no larger than its target node.

Non-Member Functions

<i>int</i>	$\text{orientation}(const\ line\&\ l, const\ point\&\ p)$	computes $\text{orientation}(a, b, p)$, where $a \neq b$ and <i>a</i> and <i>b</i> appear in this order on line <i>l</i> .
------------	---	---

15.5 Circles (`circle`)

1. Definition

An instance C of the data type *circle* is an oriented circle in the plane passing through three points p_1, p_2, p_3 . The orientation of C is equal to the orientation of the three defining points, i.e. $orientation(p_1, p_2, p_3)$. If $|\{p_1, p_2, p_3\}| = 1$ C is the empty circle with center p_1 . If p_1, p_2, p_3 are collinear C is a straight line passing through p_1, p_2 and p_3 in this order and the center of C is undefined.

```
#include < LEDA/geo/circle.h >
```

2. Types

`circle::coord_type` the coordinate type (*double*).

`circle::point_type` the point type (*point*).

3. Creation

```
circle C(const point& a, const point& b, const point& c);
```

introduces a variable C of type *circle*. C is initialized to the oriented circle through points a, b , and c .

```
circle C(const point& a, const point& b);
```

introduces a variable C of type *circle*. C is initialized to the counter-clockwise oriented circle with center a passing through b .

```
circle C(const point& a); introduces a variable  $C$  of type circle.  $C$  is initialized to the trivial circle with center  $a$ .
```

```
circle C; introduces a variable  $C$  of type circle.  $C$  is initialized to the trivial circle with center  $(0, 0)$ .
```

```
circle C(const point& c, double r);
```

introduces a variable C of type *circle*. C is initialized to the circle with center c and radius r with positive (i.e. counter-clockwise) orientation.

```
circle C(double x, double y, double r);
```

introduces a variable C of type *circle*. C is initialized to the circle with center (x, y) and radius r with positive (i.e. counter-clockwise) orientation.

circle $C(\text{const circle}\& c, \text{int});$

introduces a variable C of type *circle*. C is initialized to a copy of c . The second argument is for compatibility with *rat_circle*.

4. Operations

<i>point</i>	$C.\text{center}()$	returns the center of C . <i>Precondition:</i> The orientation of C is not 0.
<i>double</i>	$C.\text{radius}()$	returns the radius of C . <i>Precondition:</i> The orientation of C is not 0.
<i>double</i>	$C.\text{sqr_radius}()$	returns the squared radius of C . <i>Precondition:</i> The orientation of C is not 0.
<i>point</i>	$C.\text{point1}()$	returns p_1 .
<i>point</i>	$C.\text{point2}()$	returns p_2 .
<i>point</i>	$C.\text{point3}()$	returns p_3 .
<i>point</i>	$C.\text{point_on_circle}(\text{double } \alpha, \text{double } = 0)$	returns a point p on C with angle of α . The second argument is for compatibility with <i>rat_circle</i> .
<i>bool</i>	$C.\text{is_degenerate}()$	returns true if the defining points are collinear.
<i>bool</i>	$C.\text{is_trivial}()$	returns true if C has radius zero.
<i>bool</i>	$C.\text{is_line}()$	returns true if C is a line.
<i>line</i>	$C.\text{to_line}()$	returns $\text{line}(\text{point1}(), \text{point3}())$.
<i>int</i>	$C.\text{orientation}()$	returns the orientation of C .
<i>int</i>	$C.\text{side_of}(\text{const point}\& p)$	returns -1 , $+1$, or 0 if p lies right of, left of, or on C respectively.
<i>bool</i>	$C.\text{inside}(\text{const point}\& p)$	returns true iff p lies inside of C .
<i>bool</i>	$C.\text{outside}(\text{const point}\& p)$	returns true iff p lies outside of C .
<i>bool</i>	$C.\text{contains}(\text{const point}\& p)$	returns true iff p lies on C .
<i>circle</i>	$C.\text{translate_by_angle}(\text{double } a, \text{double } d)$	returns C translated in direction a by distance d .

<i>circle</i>	<i>C.translate(double dx, double dy)</i>	returns <i>C</i> translated by vector (dx, dy) .
<i>circle</i>	<i>C.translate(const vector& v)</i>	returns <i>C</i> translated by vector <i>v</i> .
<i>circle</i>	<i>C + const vector& v</i>	returns <i>C</i> translated by vector <i>v</i> .
<i>circle</i>	<i>C - const vector& v</i>	returns <i>C</i> translated by vector $-v$.
<i>circle</i>	<i>C.rotate(const point& q, double a)</i>	returns <i>C</i> rotated about point <i>q</i> by angle <i>a</i> .
<i>circle</i>	<i>C.rotate(double a)</i>	returns <i>C</i> rotated about the origin by angle <i>a</i> .
<i>circle</i>	<i>C.rotate90(const point& q, int i = 1)</i>	returns <i>C</i> rotated about <i>q</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
<i>circle</i>	<i>C.reflect(const point& p, const point& q)</i>	returns <i>C</i> reflected across the straight line passing through <i>p</i> and <i>q</i> .
<i>circle</i>	<i>C.reflect(const point& p)</i>	returns <i>C</i> reflected across point <i>p</i> .
<i>circle</i>	<i>C.reverse()</i>	returns <i>C</i> reversed.
<i>list<point></i>	<i>C.intersection(const circle& D)</i>	returns $C \cap D$ as a list of points.
<i>list<point></i>	<i>C.intersection(const line& l)</i>	returns $C \cap l$ as a list of (zero, one, or two) points sorted along <i>l</i> .
<i>list<point></i>	<i>C.intersection(const segment& s)</i>	returns $C \cap s$ as a list of (zero, one, or two) points sorted along <i>s</i> .
<i>segment</i>	<i>C.left_tangent(const point& p)</i>	returns the line segment starting in <i>p</i> tangent to <i>C</i> and left of segment $[p, C.center())$.
<i>segment</i>	<i>C.right_tangent(const point& p)</i>	returns the line segment starting in <i>p</i> tangent to <i>C</i> and right of segment $[p, C.center())$.
<i>double</i>	<i>C.distance(const point& p)</i>	returns the distance between <i>C</i> and <i>p</i> .

15.6 Polygons (POLYGON)

1. Definition

There are three instantiations of *POLYGON*: *polygon* (floating point kernel), *rat_polygon* (rational kernel) and *real_polygon* (real kernel). The respective header file name corresponds to the type name (with “.h” appended).

An instance P of the data type *POLYGON* is a cyclic list of points (equivalently segments) in the plane. A polygon is called *simple* if all nodes of the graph induced by its segments have degree two and it is called weakly simple, if its segments are disjoint except for common endpoints and if the chain does not cross itself. See the LEDA book for more details.

A weakly simple polygon splits the plane into an unbounded region and one or more bounded regions. For a simple polygon there is just one bounded region. When a weakly simple polygon P is traversed either the bounded region is consistently to the left of P or the unbounded region is consistently to the left of P . We say that P is positively oriented in the former case and negatively oriented in the latter case. We use P to also denote the region to the left of P and call this region the positive side of P .

The number of vertices is called the size of P . A polygon with empty vertex sequence is called empty.

Only the types *rat_polygon* and *real_polygon* guarantee correct results. Almost all operations listed below are available for all the three instantiations of *POLYGON*. There is a small number of operations that are only available for *polygon*, they are indicated as such.

```
#include < LEDA/geo/generic/POLYGON.h >
```

2. Types

POLYGON::*coord_type* the coordinate type (e.g. *rational*).

POLYGON::*point_type* the point type (e.g. *rat_point*).

POLYGON::*segment_type* the segment type (e.g. *rat_segment*).

POLYGON::*float_type* the corresponding floating-point type (*polygon*).

3. Creation

POLYGON P ; introduces a variable P of type *POLYGON*. P is initialized to the empty polygon.

```
POLYGON P(const list<POINT>& pl,
          CHECK_TYPE check = POLYGON::WEAKLY_SIMPLE,
          RESPECT_TYPE respect_orientation =
          POLYGON::RESPECT_ORIENTATION);
```

introduces a variable P of type $POLYGON$. P is initialized to the polygon with vertex sequence pl . If $respect_orientation$ is $DISREGARD_ORIENTATION$, the positive orientation is chosen.

Precondition: If $check$ is $SIMPLE$, pl must define a simple polygon, and if $check$ is $WEAKLY_SIMPLE$, pl must define a weakly simple polygon. If no test is to be performed, the second argument has to be set to NO_CHECK . The constants NO_CHECK , $SIMPLE$, and $WEAKLY_SIMPLE$ are part of a local enumeration type $CHECK_TYPE$.

```
POLYGON P(const polygon& Q, int prec = rat_point::default_precision);
```

introduces a variable P of type $POLYGON$. P is initialized to a rational approximation of the (floating point) polygon Q of coordinates with denominator at most $prec$. If $prec$ is zero, the implementation chooses $prec$ large enough such that there is no loss of precision in the conversion.

4. Operations

<i>polygon</i>	$P.to_float()$	returns a floating point approximation of P .
<i>void</i>	$P.normalize()$	simplifies the homogenous representation by calling $p.normalize()$ for every vertex p of P .
<i>bool</i>	$P.is_simple()$	tests whether P is simple or not.
<i>bool</i>	$P.is_weakly_simple()$	tests whether P is weakly simple or not.
<i>bool</i>	$P.is_weakly_simple(list<POINT>& L)$	as above, returns all proper points of intersection in L .
	$POLYGON::CHECK_TYPE P.check_simplicity()$	returns the $CHECK_TYPE$ of P . The result can be $SIMPLE$, $WEAKLY_SIMPLE$ or NOT_WEAKLY_SIMPLE .
<i>bool</i>	$P.is_convex()$	returns true if P is convex, false otherwise.
<i>const list<POINT>&</i>	$P.vertices()$	returns the sequence of vertices of P in counter-clockwise ordering.

<i>const list<SEGMENT>&</i>	<i>P.segments()</i>	returns the sequence of bounding segments of <i>P</i> in counter-clockwise ordering.
<i>list<POINT></i>	<i>P.intersection(const SEGMENT& s)</i>	returns the proper crossings between <i>P</i> and <i>s</i> as a list of points.
<i>list<POINT></i>	<i>P.intersection(const LINE& l)</i>	returns the proper crossings between <i>P</i> and <i>l</i> as a list of points.
<i>POLYGON</i>	<i>P.intersect_halfplane(const LINE& l)</i>	returns the intersection of <i>P</i> with the half-space on the positive side of <i>l</i> .
<i>int</i>	<i>P.size()</i>	returns the size of <i>P</i> .
<i>bool</i>	<i>P.empty()</i>	returns true if <i>P</i> is empty, false otherwise.
<i>POLYGON</i>	<i>P.translate(RAT_TYPE dx, RAT_TYPE dy)</i>	returns <i>P</i> translated by vector (dx, dy) .
<i>POLYGON</i>	<i>P.translate(INT_TYPE dx, INT_TYPE dy, INT_TYPE dw)</i>	returns <i>P</i> translated by vector $(dx/dw, dy/dw)$.
<i>POLYGON</i>	<i>P.translate(const VECTOR& v)</i>	returns <i>P</i> translated by vector <i>v</i> .
<i>POLYGON</i>	<i>P + const VECTOR& v</i>	returns <i>P</i> translated by vector <i>v</i> .
<i>POLYGON</i>	<i>P - const VECTOR& v</i>	returns <i>P</i> translated by vector $-v$.
<i>POLYGON</i>	<i>P.rotate90(const POINT& q, int i = 1)</i>	returns <i>P</i> rotated about <i>q</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
<i>POLYGON</i>	<i>P.reflect(const POINT& p, const POINT& q)</i>	returns <i>P</i> reflected across the straight line passing through <i>p</i> and <i>q</i> .
<i>POLYGON</i>	<i>P.reflect(const POINT& p)</i>	returns <i>P</i> reflected across point <i>p</i> .
<i>RAT_TYPE</i>	<i>P.sqr_dist(const POINT& p)</i>	returns the square of the minimal Euclidean distance between a segment in <i>P</i> and <i>p</i> . Returns zero if <i>P</i> is empty.

- POLYGON* *P.complement()* returns the complement of *P*.
- POLYGON* *P.eliminate_colinear_vertices()*
returns a copy of *P* without colinear vertices.
- list<POLYGON>* *P.simple_parts()* returns the simple parts of *P* as a list of simple polygons.
- list<POLYGON>* *P.split_into_weakly_simple_parts(bool strict = false)*
splits *P* into a set of weakly simple polygons whose union coincides with the inner points of *P*. If *strict* is true a point is considered an inner point if it is left of all surrounding segments, otherwise it is considered as an inner point if it is locally to the left of some surrounding edge. (This function is experimental.)
- GEN_POLYGON* *P.make_weakly_simple(bool with_neg_parts = true, bool strict = false)*
creates a weakly simple generalized polygon *Q* from a possibly non-simple polygon *P* such that *Q* and *P* have the same inner points. The flag *with_neg_parts* determines whether inner points in negatively oriented parts are taken into account, too. The meaning of the flag *strict* is the same as in the method above. (This function is experimental.)
- GEN_POLYGON* *P.buffer(RAT_TYPE d, int p)*
adds an exterior buffer zone to *P* ($d > 0$), or removes an interior buffer zone from *P* ($d < 0$). More precisely, for $d \geq 0$ define the buffer tube *T* as the set of all points in the complement of *P* whose distance to *P* is at most *d*. Then the function returns $P \cup T$. For $d < 0$ let *T* denote the set of all points in *P* whose distance to the complement is less than $|d|$. Then the result is $P \setminus T$. *p* specifies the number of points used to represent convex corners. At the moment, only $p = 1$ and $p = 3$ are supported. (This function is experimental.)

The functions in the following group are only available for *polygons*. They have no counterpart for *rat_polygons*.

<i>polygon</i>	<i>P.translate_by_angle(double alpha, double d)</i>	returns <i>P</i> translated in direction <i>alpha</i> by distance <i>d</i> .
<i>polygon</i>	<i>P.rotate(const point& p, double alpha)</i>	returns <i>P</i> rotated by α degrees about <i>p</i> .
<i>polygon</i>	<i>P.rotate(double alpha)</i>	returns <i>P</i> rotated by α degrees about the origin.
<i>double</i>	<i>P.distance(const point& p)</i>	returns the Euclidean distance between <i>P</i> and <i>p</i> .
<i>rat_polygon</i>	<i>P.to_rational(int prec = -1)</i>	returns a representation of <i>P</i> with rational coordinates with precision <i>prec</i> (cf. Section 15.10).

All functions below assume that *P* is weakly simple.

<i>int</i>	<i>P.side_of(const POINT& p)</i>	returns +1 if <i>p</i> lies to the left of <i>P</i> , 0 if <i>p</i> lies on <i>P</i> , and -1 if <i>p</i> lies to the right of <i>P</i> .
<i>region_kind</i>	<i>P.region_of(const POINT& p)</i>	returns BOUNDED_REGION if <i>p</i> lies in the bounded region of <i>P</i> , returns ON_REGION if <i>p</i> lies on <i>P</i> , and returns UNBOUNDED_REGION if <i>p</i> lies in the unbounded region.
<i>bool</i>	<i>P.inside(const POINT& p)</i>	returns true if <i>p</i> lies to the left of <i>P</i> , i.e., <i>side_of(p) == +1</i> .
<i>bool</i>	<i>P.on_boundary(const POINT& p)</i>	returns true if <i>p</i> lies on <i>P</i> , i.e., <i>side_of(p) == 0</i> .
<i>bool</i>	<i>P.outside(const POINT& p)</i>	returns true if <i>p</i> lies to the right of <i>P</i> , i.e., <i>side_of(p) == -1</i> .
<i>bool</i>	<i>P.contains(const POINT& p)</i>	returns true if <i>p</i> lies to the left of or on <i>P</i> .

<i>RAT_TYPE</i>	<i>P</i> .area()	returns the signed area of the bounded region of <i>P</i> . The sign of the area is positive if the bounded region is the positive side of <i>P</i> .
<i>int</i>	<i>P</i> .orientation()	returns the orientation of <i>P</i> .
<i>void</i>	<i>P</i> .bounding_box(<i>POINT</i> & <i>xmin</i> , <i>POINT</i> & <i>ymin</i> , <i>POINT</i> & <i>xmax</i> , <i>POINT</i> & <i>ymax</i>)	returns the coordinates of a rectangular bounding box of <i>P</i> .

Iterations Macros

forall_vertices(*v*, *P*) { “the vertices of *P* are successively assigned to *rat_point v*” }

forall_segments(*s*, *P*) { “the edges of *P* are successively assigned to *rat_segment s*” }

Non-Member Functions

POLYGON **reg_ngon**(*int n*, *CIRCLE C*, *double epsilon*)

generates a (nearly) regular *n*-gon whose vertices lie on the circle *C*. The *i*-th point is generated by *C.point_of_circle*($2\pi i/n$, *epsilon*). With the rational kernel the vertices of the *n*-gon are guaranteed to lie on the circle, with the floating point kernel they are only guaranteed to lie near *C*.

POLYGON **n_gon**(*int n*, *CIRCLE C*, *double epsilon*)

generates a (nearly) regular *n*-gon whose vertices lie near the circle *C*. For the floating point kernel the function is equivalent to the function above. For the rational kernel the function first generates a *n*-gon with floating point arithmetic and then converts the resulting *polygon* to a *rat_polygon*.

POLYGON **hilbert**(*int n*, *RAT_TYPE x1*, *RAT_TYPE y1*, *RAT_TYPE x2*, *RAT_TYPE y2*)

generates the Hilbert polygon of order *n* within the rectangle with boundary (*x1*, *y1*) and (*x2*, *y2*).
Precondition: x1 < x2 and y1 < y2.

15.7 Generalized Polygons (GEN_POLYGON)

1. Definition

There are three instantiations of *POLYGON*: *gen_polygon* (floating point kernel), *rat_gen_polygon* (rational kernel) and *real_gen_polygon* (real kernel). The respective header file name corresponds to the type name (with “.h” appended).

An instance P of the data type *GEN_POLYGON* is a regular polygonal region in the plane. A regular region is an open set that is equal to the interior of its closure. A region is polygonal if its boundary consists of a finite number of line segments.

The boundary of a *GEN_POLYGON* consists of zero or more weakly simple closed polygonal chains. There are two regions whose boundary is empty, namely the empty region and the full region. The full region encompasses the entire plane. We call a region non-trivial if its boundary is non-empty. The boundary cycles P_1, P_2, \dots, P_k of a *GEN_POLYGON* are ordered such that no P_i is nested in a P_j with $i < j$.

Only the types *rat_polygon* and *real_polygon* guarantee correct results. Almost all operations listed below are available for all the three instantiations of *POLYGON*. There is a small number of operations that are only available for *polygon*, they are indicated as such.

A detailed discussion of polygons and generalized polygons can be found in the LEDA book.

The local enumeration type *KIND* consists of elements *EMPTY*, *FULL*, and *NON_TRIVIAL*.

```
#include < LEDA/geo/generic/GEN_POLYGON.h >
```

2. Types

GEN_POLYGON :: *coord_type*

the coordinate type (e.g. *rational*).

GEN_POLYGON :: *point_type*

the point type (e.g. *rat_point*).

GEN_POLYGON :: *segment_type*

the segment type (e.g. *rat_segment*).

GEN_POLYGON :: *polygon_type*

the polygon type (e.g. *rat_polygon*).

GEN_POLYGON :: *float_type*

the corresponding floating-point type (*gen_polygon*).

3. Creation

GEN_POLYGON *P*(*KIND* *k* = *GEN_POLYGON_REP*::*EMPTY*);

introduces a variable *P* of type *GEN_POLYGON*. *P* is initialized to the empty polygon if *k* is *EMPTY* and to the full polygon if *k* is *FULL*.

GEN_POLYGON *P*(*const POLYGON*& *p*,
CHECK_TYPE *check* = *WEAKLY_SIMPLE*,
RESPECT_TYPE *respect_orientation* =
RESPECT_ORIENTATION);

introduces a variable *P* of type *GEN_POLYGON*. *P* is initialized to the polygonal region with boundary *p*. If *respect_orientation* is *DISREGARD_ORIENTATION*, the orientation is chosen such *P* is bounded.

Precondition: *p* must be a weakly simple polygon. If *check* is set appropriately this is checked.

GEN_POLYGON *P*(*const list<POINT>*& *pl*,
CHECK_TYPE *check* = *GEN_POLYGON*::*WEAKLY_SIMPLE*,
RESPECT_TYPE *respect_orientation* =
RESPECT_ORIENTATION);

introduces a variable *P* of type *GEN_POLYGON*. *P* is initialized to the polygon with vertex sequence *pl*. If *respect_orientation* is *DISREGARD_ORIENTATION*, the orientation is chosen such that *P* is bounded.

Precondition: If *check* is *SIMPLE*, *pl* must define a simple polygon, and if *check* is *WEAKLY_SIMPLE*, *pl* must define a weakly simple polygon. If no test is to performed, the second argument has to be set to *NO_CHECK*. The three constants *NO_CHECK*, *SIMPLE*, and *WEAKLY_SIMPLE* are part of a local enumeration type *CHECK_TYPE*.

GEN_POLYGON *P*(*const list<POLYGON>*& *PL*,
CHECK_TYPE *check* = *CHECK_REP*);

introduces a variable *P* of type *GEN_POLYGON*. *P* is initialized to the polygon with boundary representation *PL*.

Precondition: *PL* must be a boundary representation. This conditions is checked if *check* is set to *CHECK_REP*.

GEN_POLYGON *P*(*const list<GEN_POLYGON>*& *PL*);

introduces a variable *P* of type *GEN_POLYGON*. *P* is initialized to the union of all generalized polygons in *PL*.

GEN_POLYGON $P(\text{const } \textit{gen_polygon}\& Q, \textit{int } \textit{prec} = \textit{rat_point}::\textit{default_precision});$

introduces a variable P of type *GEN_POLYGON*. P is initialized to a rational approximation of the (floating point) polygon Q of coordinates with denominator at most \textit{prec} . If \textit{prec} is zero, the implementation chooses \textit{prec} large enough such that there is no loss of precision in the conversion

4. Operations

<i>bool</i>	$P.\textit{empty}()$	returns true if P is empty, false otherwise.
<i>bool</i>	$P.\textit{full}()$	returns true if P is the entire plane, false otherwise.
<i>bool</i>	$P.\textit{trivial}()$	returns true if P is either empty or full, false otherwise.
<i>bool</i>	$P.\textit{is_convex}()$	returns true if P is convex, false otherwise.
<i>KIND</i>	$P.\textit{kind}()$	returns the kind of P .
<i>gen_polygon</i>	$P.\textit{to_float}()$	returns a floating point approximation of P .
<i>void</i>	$P.\textit{normalize}()$	simplifies the homogenous representation by calling $p.\textit{normalize}()$ for every vertex p of P .
<i>bool</i>	$P.\textit{is_simple}()$	returns true if the polygonal region is simple, i.e., if the graph defined by the segments in the boundary of P has only vertices of degree two.
<i>bool</i>	$\textit{GEN_POLYGON}::\textit{check_representation}(\textit{const } \textit{list}\langle\textit{POLYGON}\rangle\& PL)$	checks whether PL is a boundary representation.
<i>bool</i>	$P.\textit{check_representation}()$	tests whether the representation of P is OK. This test is partial.
<i>void</i>	$P.\textit{canonical_rep}()$	NOT IMPLEMENTED YET.
$\textit{list}\langle\textit{POINT}\rangle$	$P.\textit{vertices}()$	returns the concatenated vertex lists of all polygons in the boundary representation of P .

- list<SEGMENT>* *P.edges()* returns the concatenated edge lists of all polygons in the boundary representation of *P*.
Please note that it is not save to use this function in a forall-loop. Instead of writing forall(SEGMENT *s*, edges()).. please write list<SEGMENT> *L* = edges(); forall(SEGMENT *s*, *L*)....
- const list<POLYGON>&* *P.polygons()* returns the lists of all polygons in the boundary representation of *P*.
- list<POINT>* *P.intersection(const SEGMENT& s)* returns the list of all proper intersections between *s* and the boundary of *P*.
- list<POINT>* *P.intersection(const LINE& l)* returns the list of all proper intersections between *l* and the boundary of *P*.
- int* *P.size()* returns the number of segments in the boundary of *P*.
- GEN_POLYGON* *P.translate(RAT_TYPE dx, RAT_TYPE dy)* returns *P* translated by vector (*dx*, *dy*).
- GEN_POLYGON* *P.translate(INT_TYPE dx, INT_TYPE dy, INT_TYPE dw)* returns *P* translated by vector (*dx/dw*, *dy/dw*).
- GEN_POLYGON* *P.translate(const VECTOR& v)* returns *P* translated by vector *v*.
- GEN_POLYGON* *P + const VECTOR& v* returns *P* translated by vector *v*.
- GEN_POLYGON* *P - const VECTOR& v* returns *P* translated by vector $-v$.
- GEN_POLYGON* *P.rotate90(const POINT& q, int i = 1)* returns *P* rotated about *q* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- GEN_POLYGON* *P.reflect(const POINT& p, const POINT& q)* returns *P* reflected across the straight line passing through *p* and *q*.
- GEN_POLYGON* *P.reflect(const POINT& p)* returns *P* reflected across point *p*.

- RAT_TYPE* *P.sqr_dist(const POINT& p)*
 returns the square of the minimal Euclidean distance between a segment in the boundary of *P* and *p*. Returns zero if *P* is trivial.
- GEN_POLYGON* *P.make_weakly_simple(bool with_neg_parts = true, bool strict = false)*
 creates a weakly simple generalized polygon *Q* from a possibly non-simple polygon *P* such that *Q* and *P* have the same inner points. The flag *with_neg_parts* determines whether inner points in negatively oriented parts are taken into account, too. If *strict* is true a point is considered an inner point if it is left of all surrounding segments, otherwise it is considered as an inner point if it is locally to the left of some surrounding edge. (This function is experimental.)
- GEN_POLYGON* *GEN_POLYGON::make_weakly_simple(const POLYGON& Q, bool with_neg_parts = true, bool strict = false)*
 same as above but the input is a polygon *Q*. (This function is experimental.)
- GEN_POLYGON* *P.complement()* returns the complement of *P*.
- GEN_POLYGON* *P.eliminate_colinear_vertices()*
 returns a copy of *P* without colinear vertices.
- int* *P.side_of(const POINT& p)*
 returns +1 if *p* lies to the left of *P*, 0 if *p* lies on *P*, and -1 if *p* lies to the right of *P*.
- region_kind* *P.region_of(const POINT& p)*
 returns *BOUNDED_REGION* if *p* lies in the bounded region of *P*, returns *ON_REGION* if *p* lies on *P*, and returns *UNBOUNDED_REGION* if *p* lies in the unbounded region. The bounded region of the full polygon is the entire plane.
- bool* *P.inside(const POINT& p)*
 returns true if *p* lies to the left of *P*, i.e., *side_of(p) == +1*.

<i>bool</i>	<i>P.on_boundary(const POINT& p)</i>	returns true if <i>p</i> lies on <i>P</i> , i.e., <i>side_of(p) == 0</i> .
<i>bool</i>	<i>P.outside(const POINT& p)</i>	returns true if <i>p</i> lies to the right of <i>P</i> , i.e., <i>side_of(p) == -1</i> .
<i>bool</i>	<i>P.contains(const POINT& p)</i>	returns true if <i>p</i> lies to the left of or on <i>P</i> .
<i>RAT_TYPE</i>	<i>P.area()</i>	returns the signed area of the bounded region of <i>P</i> . The sign of the area is positive if the bounded region is the positive side of <i>P</i> . <i>Precondition:</i> <i>P</i> is not the full polygon.
<i>int</i>	<i>P.orientation()</i>	returns the orientation of <i>P</i> .
<i>list<GEN_POLYGON></i>	<i>P.regionaldecomposition()</i>	computes a decomposition of the bounded region of <i>P</i> into simple connected components P_1, \dots, P_n . If <i>P</i> is trivial the decomposition is <i>P</i> itself. Otherwise, the boundary of every P_i consists of an exterior polygon and zero or more holes nested inside. But the holes do not contain any nested polygons. (Note that <i>P</i> may have holes containing nested polygons; they appear as separate components in the decomposition.) Every P_i has the same orientation as <i>P</i> . If it is positive then <i>P</i> is the union of P_1, \dots, P_n , otherwise <i>P</i> is the intersection of P_1, \dots, P_n .
<i>GEN_POLYGON</i>	<i>P.buffer(RAT_TYPE d, int p = 3)</i>	adds an exterior buffer zone to <i>P</i> ($d > 0$), or removes an interior buffer zone from <i>P</i> ($d < 0$). More precisely, for $d \geq 0$ define the buffer tube <i>T</i> as the set of all points in the complement of <i>P</i> whose distance to <i>P</i> is at most <i>d</i> . Then the function returns $P \cup T$. For $d < 0$ let <i>T</i> denote the set of all points in <i>P</i> whose distance to the complement is less than $ d $. Then the result is $P \setminus T$. <i>p</i> specifies the number of points used to represent convex corners. At the moment, only $p = 1$ and $p = 3$ are supported. (This function is experimental.)

All binary boolean operations are regularized, i.e., the result R of the standard boolean operation is replaced by the interior of the closure of R . We use $\text{reg } X$ to denote the regularization of a set X .

GEN_POLYGON $P.\text{unite}(\text{const } GEN_POLYGON \& Q)$
returns $\text{reg}(P \cup Q)$.

GEN_POLYGON $P.\text{intersection}(\text{const } GEN_POLYGON \& Q)$
returns $\text{reg}(P \cap Q)$.

GEN_POLYGON $P.\text{diff}(\text{const } GEN_POLYGON \& Q)$
returns $\text{reg}(P \setminus Q)$.

GEN_POLYGON $P.\text{sym_diff}(\text{const } GEN_POLYGON \& Q)$
returns $\text{reg}((P \cup Q) - (P \cap Q))$.

The following functions are only available for *gen_polygons*. They have no counterpart for *rat_gen_polygons* or *real_gen_polygons*.

gen_polygon $P.\text{translate_by_angle}(\text{double } alpha, \text{double } d)$
returns P translated in direction $alpha$ by distance d .

gen_polygon $P.\text{rotate}(\text{const } point \& p, \text{double } alpha)$
returns P rotated by α degrees about p .

gen_polygon $P.\text{rotate}(\text{double } alpha)$ returns P rotated by α degrees about the origin.

double $P.\text{distance}(\text{const } point \& p)$
returns the Euclidean distance between P and p .

rat_gen_polygon $P.\text{to_rational}(\text{int } prec = -1)$
returns a representation of P with rational coordinates with precision $prec$ (cf. Section 15.10).

Iterations Macros

forall_polygons(p, P) { “the boundary polygons of P are successively assigned to POLYGON p ” }

15.8 Triangles (triangle)

1. Definition

An instance t of the data type *triangle* is an oriented triangle in the two-dimensional plane. A triangle splits the plane into one bounded and one unbounded region. If the triangle is positively oriented, the bounded region is to the left of it, if it is negatively oriented, the unbounded region is to the left of it. A triangle t is called degenerate, if the 3 vertices of t are collinear.

```
#include < LEDA/geo/triangle.h >
```

2. Types

triangle::*coord_type* the coordinate type (*double*).

triangle::*point_type* the point type (*point*).

3. Creation

triangle t ; introduces a variable t of type *triangle*. t is initialized to the empty triangle.

triangle $t(\text{const } \textit{point}\& p, \text{const } \textit{point}\& q, \text{const } \textit{point}\& r)$; introduces a variable t of type *triangle*. t is initialized to the triangle $[p, q, r]$.

triangle $t(\text{double } x1, \text{double } y1, \text{double } x2, \text{double } y2, \text{double } x3, \text{double } y3)$; introduces a variable t of type *triangle*. t is initialized to the triangle $[(x1, y1), (x2, y2), (x3, y3)]$.

4. Operations

point $t.\text{point1}()$ returns the first vertex of triangle t .

point $t.\text{point2}()$ returns the second vertex of triangle t .

point $t.\text{point3}()$ returns the third vertex of triangle t .

point $t[\textit{int } i]$ returns the i -th vertex of t . *Precondition*: $1 \leq i \leq 3$.

int $t.\text{orientation}()$ returns the orientation of t .

double $t.\text{area}()$ returns the signed area of t (positive, if *orientation*(a, b, c) > 0, negative otherwise).

bool $t.\text{is_degenerate}()$ returns true if the vertices of t are collinear.

- int* *t.side_of(const point& p)*
 returns +1 if *p* lies to the left of *t*, 0 if *p* lies on *t* and -1 if *p* lies to the right of *t*.
- region_kind* *t.region_of(const point& p)*
 returns *BOUNDED_REGION* if *p* lies in the bounded region of *t*, *ON_REGION* if *p* lies on *t* and *UNBOUNDED_REGION* if *p* lies in the unbounded region.
- bool* *t.inside(const point& p)*
 returns true, if *p* lies to the left of *t*.
- bool* *t.outside(const point& p)*
 returns true, if *p* lies to the right of *t*.
- bool* *t.on_boundary(const point& p)*
 decides whether *p* lies on the boundary of *t*.
- bool* *t.contains(const point& p)*
 decides whether *t* contains *p*.
- bool* *t.intersection(const line& l)*
 decides whether the bounded region or the boundary of *t* and *l* intersect.
- bool* *t.intersection(const segment& s)*
 decides whether the bounded region or the boundary of *t* and *s* intersect.
- triangle* *t.translate(double dx, double dy)*
 returns *t* translated by vector (dx, dy) .
- triangle* *t.translate(const vector& v)*
 returns $t + v$, i.e., *t* translated by vector *v*.
Precondition: $v.\text{dim}() = 2$.
- triangle* $t + \text{const vector\& } v$
 returns *t* translated by vector *v*.
- triangle* $t - \text{const vector\& } v$
 returns *t* translated by vector $-v$.
- triangle* *t.rotate(const point& q, double a)*
 returns *t* rotated about point *q* by angle *a*.
- triangle* *t.rotate(double alpha)*
 returns $t.\text{rotate}(t.\text{point1}(), \text{alpha})$.

triangle `t.rotate90(const point& q, int i = 1)`

returns *t* rotated about *q* by an angle of $i \times 90$ degrees.
If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

triangle `t.rotate90(int i = 1)`

returns `t.rotate90(t.source(),i)`.

triangle `t.reflect(const point& p, const point& q)`

returns *t* reflected across the straight line passing through *p* and *q*.

triangle `t.reflect(const point& p)`

returns *t* reflected across point *p*.

triangle `t.reverse()`

returns *t* reversed.

15.9 Iso-oriented Rectangles (`rectangle`)

1. Definition

An instance r of the data type *rectangle* is an iso-oriented rectangle in the two-dimensional plane.

```
#include <LEDA/geo/rectangle.h >
```

2. Creation

```
rectangle r(const point& p, const point& q);
```

introduces a variable r of type *rectangle*. r is initialized to the *rectangle* with diagonal corners p and q

```
rectangle r(const point& p, double w, double h);
```

introduces a variable r of type *rectangle*. r is initialized to the *rectangle* with lower left corner p , width w and height h .

```
rectangle r(double x1, double y1, double x2, double y2);
```

introduces a variable r of type *rectangle*. r is initialized to the *rectangle* with diagonal corners $(x1, y1)$ and $(x2, y2)$.

3. Operations

point r .upper_left() returns the upper left corner.

point r .upper_right() returns the upper right corner.

point r .lower_left() returns the lower left corner.

point r .lower_right() returns the lower right corner.

point r .center() returns the center of r .

list<*point*> r .vertices() returns the vertices of r in counter-clockwise order starting from the lower left point.

double r .xmin() returns the minimal x-coordinate of r .

double r .xmax() returns the maximal x-coordinate of r .

double r .ymin() returns the minimal y-coordinate of r .

double r .ymax() returns the maximal y-coordinate of r .

double r .width() returns the width of r .

<i>double</i>	<i>r.height()</i>	returns the height of <i>r</i> .
<i>bool</i>	<i>r.is_degenerate()</i>	returns true, if <i>r</i> degenerates to a segment or point (the 4 corners are collinear), false otherwise.
<i>bool</i>	<i>r.is_point()</i>	returns true, if <i>r</i> degenerates to a point.
<i>bool</i>	<i>r.is_segment()</i>	returns true, if <i>r</i> degenerates to a segment.
<i>int</i>	<i>r.cs_code(const point& p)</i>	returns the code for Cohen-Sutherland algorithm.
<i>bool</i>	<i>r.inside(const point& p)</i>	returns true, if <i>p</i> is inside of <i>r</i> , false otherwise.
<i>bool</i>	<i>r.outside(const point& p)</i>	returns true, if <i>p</i> is outside of <i>r</i> , false otherwise.
<i>bool</i>	<i>r.inside_or_contains(const point& p)</i>	returns true, if <i>p</i> is inside of <i>r</i> or on the border, false otherwise.
<i>bool</i>	<i>r.contains(const point& p)</i>	returns true, if <i>p</i> is on the border of <i>r</i> , false otherwise.
<i>region_kind</i>	<i>r.region_of(const point& p)</i>	returns BOUNDED_REGION if <i>p</i> lies in the bounded region of <i>r</i> , returns ON_REGION if <i>p</i> lies on <i>r</i> , and returns UNBOUNDED_REGION if <i>p</i> lies in the unbounded region.
<i>rectangle</i>	<i>r.include(const point& p)</i>	returns a new rectangle that includes the points of <i>r</i> and <i>p</i> .
<i>rectangle</i>	<i>r.include(const rectangle& r2)</i>	returns a new rectangle that includes the points of <i>r</i> and <i>r2</i> .
<i>rectangle</i>	<i>r.translate(double dx, double dy)</i>	returns a new rectangle that is the translation of <i>r</i> by (<i>dx</i> , <i>dy</i>).
<i>rectangle</i>	<i>r.translate(const vector& v)</i>	returns a new rectangle that is the translation of <i>r</i> by <i>v</i> .
<i>rectangle</i>	<i>r + const vector& v</i>	returns <i>r</i> translated by <i>v</i> .
<i>rectangle</i>	<i>r - const vector& v</i>	returns <i>r</i> translated by $-v$.
<i>point</i>	<i>r[int i]</i>	returns the <i>i</i> - th vertex of <i>r</i> . Precondition: ($0 < i < 5$).

- rectangle* `r.rotate90(const point& p, int i = 1)`
 returns *r* rotated about *p* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- rectangle* `r.rotate90(int i = 1)` returns *r* rotated by an angle of $i \times 90$ degrees about the origin.
- rectangle* `r.reflect(const point& p)` returns *r* reflected across *p*.
- list<point>* `r.intersection(const segment& s)`
 returns $r \cap s$.
- bool* `r.clip(const segment& t, segment& inter)`
 clips *t* on *r* and returns the result in *inter*.
- bool* `r.clip(const line& l, segment& inter)`
 clips *l* on *r* and returns the result in *inter*.
- bool* `r.clip(const ray& ry, segment& inter)`
 clips *ry* on *r* and returns the result in *inter*.
- bool* `r.difference(const rectangle& q, list<rectangle>& L)`
 returns *true* iff the difference of *r* and *q* is not empty, and *false* otherwise. The difference *L* is returned as a partition into rectangles.
- list<point>* `r.intersection(const line& l)`
 returns $r \cap l$.
- list<rectangle>* `r.intersection(const rectangle& s)`
 returns $r \cap s$.
- bool* `r.do_intersect(const rectangle& b)`
 returns *true* iff *r* and *b* intersect, false otherwise.
- double* `r.area()` returns the area of *r*.

15.10 Rational Points (*rat_point*)

1. Definition

An instance of data type *rat_point* is a point with rational coordinates in the two-dimensional plane. A point with cartesian coordinates (a, b) is represented by homogeneous coordinates (x, y, w) of arbitrary length integers (see 6.1) such that $a = x/w$ and $b = y/w$ and $w > 0$.

```
#include < LEDA/geo/rat_point.h >
```

2. Types

rat_point::coord_type the coordinate type (*rational*).

rat_point::point_type the point type (*rat_point*).

rat_point::float_type the corresponding floating-point type (*point*).

3. Creation

rat_point *p*;
introduces a variable *p* of type *rat_point* initialized to the point $(0, 0)$.

rat_point *p*(*const rational*& *a*, *const rational*& *b*);
introduces a variable *p* of type *rat_point* initialized to the point (a, b) .

rat_point *p*(*integer* *a*, *integer* *b*);
introduces a variable *p* of type *rat_point* initialized to the point (a, b) .

rat_point *p*(*integer* *x*, *integer* *y*, *integer* *w*);
introduces a variable *p* of type *rat_point* initialized to the point with homogeneous coordinates (x, y, w) if $w > 0$ and to point $(-x, -y, -w)$ if $w < 0$.
Precondition: $w \neq 0$.

rat_point *p*(*const rat_vector*& *v*);
introduces a variable *p* of type *rat_point* initialized to the point $(v[0], v[1])$.
Precondition: $v.dim() = 2$.

rat_point $p(\text{const point\& } p_1, \text{int } prec = \text{rat_point::default_precision});$

introduces a variable p of type *rat_point* initialized to the point with homogeneous coordinates $(\lfloor P*x \rfloor, \lfloor P*y \rfloor, P)$, where $p_1 = (x, y)$ and $P = 2^{prec}$. If $prec$ is non-positive, the conversion is without loss of precision, i.e., P is chosen as a sufficiently large power of two such that $P * x$ and $P * y$ are *integers*.

rat_point $p(\text{double } x, \text{double } y, \text{int } prec = \text{rat_point::default_precision});$

see constructor above with $p = (x, y)$.

4. Operations

point $p.\text{to_float}()$ returns a floating point approximation of p .

rat_vector $p.\text{to_vector}()$ returns the vector extending from the origin to p .

void $p.\text{normalize}()$ simplifies the homogenous representation by dividing all coordinates by $\text{gcd}(X, Y, W)$.

integer $p.X()$ returns the first homogeneous coordinate of p .

integer $p.Y()$ returns the second homogeneous coordinate of p .

integer $p.W()$ returns the third homogeneous coordinate of p .

double $p.XD()$ returns a floating point approximation of $p.X()$.

double $p.YD()$ returns a floating point approximation of $p.Y()$.

double $p.WD()$ returns a floating point approximation of $p.W()$.

rational $p.\text{xcoord}()$ returns the x -coordinate of p .

rational $p.\text{ycoord}()$ returns the y -coordinate of p .

double $p.\text{xcoordD}()$ returns a floating point approximation of $p.\text{xcoord}()$.

double $p.\text{ycoordD}()$ returns a floating point approximation of $p.\text{ycoord}()$.

rat_point $p.\text{rotate90}(\text{const rat_point\& } q, \text{int } i = 1)$

returns p rotated by $i \times 90$ degrees about q . If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

rat_point $p.\text{rotate90}(\text{int } i = 1)$

returns p rotated by $i \times 90$ degrees about the origin. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

- rat_point* `p.reflect(const rat_point& p, const rat_point& q)`
 returns p reflected across the straight line passing through p and q .
Precondition: $p \neq q$.
- rat_point* `p.reflect(const rat_point& q)`
 returns p reflected across point q .
- rat_point* `p.translate(const rational& dx, const rational& dy)`
 returns p translated by vector (dx, dy) .
- rat_point* `p.translate(integer dx, integer dy, integer dw)`
 returns p translated by vector $(dx/dw, dy/dw)$.
- rat_point* `p.translate(const rat_vector& v)`
 returns $p + v$, i.e., p translated by vector v .
Precondition: $v.dim() = 2$.
- rat_point* `p + const rat_vector& v`
 returns p translated by vector v .
- rat_point* `p - const rat_vector& v`
 returns p translated by vector $-v$.
- rational* `p.sqr_dist(const rat_point& q)`
 returns the squared distance between p and q .
- int* `p.cmp_dist(const rat_point& q, const rat_point& r)`
 returns $compare(p.sqr_dist(q), p.sqr_dist(r))$.
- rational* `p.xdist(const rat_point& q)`
 returns the horizontal distance between p and q .
- rational* `p.ydist(const rat_point& q)`
 returns the vertical distance between p and q .
- int* `p.orientation(const rat_point& q, const rat_point& r)`
 returns $orientation(p, q, r)$ (see below).
- rational* `p.area(const rat_point& q, const rat_point& r)`
 returns $area(p, q, r)$ (see below).
- rat_vector* `p - const rat_point& q`
 returns the difference vector of the coordinates.

Non-Member Functions

- int* `cmp_signed_dist(const rat_point& a, const rat_point& b, const rat_point& c, const rat_point& d)`
 compares (signed) distances of c and d to the straight line passing through a and b (directed from a to b). Returns $+1$ (-1) if c has larger (smaller) distance than d and 0 if distances are equal.
- int* `orientation(const rat_point& a, const rat_point& b, const rat_point& c)`
 computes the orientation of points a, b, c as the sign of the determinant
- $$\begin{vmatrix} a_x & a_y & a_w \\ b_x & b_y & b_w \\ c_x & c_y & c_w \end{vmatrix}$$
- i.e., it returns $+1$ if point c lies left of the directed line through a and b , 0 if a, b , and c are collinear, and -1 otherwise.
- int* `cmp_distances(const rat_point& p1, const rat_point& p2, const rat_point& p3, const rat_point& p4)`
 compares the distances $(p1, p2)$ and $(p3, p4)$. Returns $+1$ (-1) if distance $(p1, p2)$ is larger (smaller) than distance $(p3, p4)$, otherwise 0 .
- rat_point* `midpoint(const rat_point& a, const rat_point& b)`
 returns the midpoint of a and b .
- rational* `area(const rat_point& a, const rat_point& b, const rat_point& c)`
 computes the signed area of the triangle determined by a, b, c , positive if $orientation(a, b, c) > 0$ and negative otherwise.
- bool* `collinear(const rat_point& a, const rat_point& b, const rat_point& c)`
 returns true if points a, b, c are collinear, i.e., $orientation(a, b, c) = 0$, and false otherwise.
- bool* `right_turn(const rat_point& a, const rat_point& b, const rat_point& c)`
 returns true if points a, b, c form a right turn, i.e., $orientation(a, b, c) < 0$, and false otherwise.
- bool* `left_turn(const rat_point& a, const rat_point& b, const rat_point& c)`
 returns true if points a, b, c form a left turn, i.e., $orientation(a, b, c) > 0$, and false otherwise.

- int* `side_of_halfspace(const rat_point& a, const rat_point& b, const rat_point& c)`
returns the sign of the scalar product $(b-a) \cdot (c-a)$. If $b \neq a$ this amounts to: Let h be the open halfspace orthogonal to the vector $b-a$, containing b , and having a in its boundary. Returns $+1$ if c is contained in h , returns 0 if c lies on the boundary of h , and returns -1 if c is contained in the interior of the complement of h .
- int* `side_of_circle(const rat_point& a, const rat_point& b, const rat_point& c,
const rat_point& d)`
returns $+1$ if point d lies left of the directed circle through points a , b , and c , 0 if $a, b, c,$ and d are cocircular, and -1 otherwise.
- bool* `incircle(const rat_point& a, const rat_point& b, const rat_point& c,
const rat_point& d)`
returns *true* if point d lies in the interior of the circle through points a , b , and c , and *false* otherwise.
- bool* `outcircle(const rat_point& a, const rat_point& b, const rat_point& c,
const rat_point& d)`
returns *true* if point d lies outside of the circle through points a , b , and c , and *false* otherwise.
- bool* `on_circle(const rat_point& a, const rat_point& b, const rat_point& c,
const rat_point& d)`
returns *true* if points a , b , c , and d are cocircular.
- bool* `cocircular(const rat_point& a, const rat_point& b, const rat_point& c,
const rat_point& d)`
returns *true* if points a , b , c , and d are cocircular.
- int* `compare_by_angle(const rat_point& a, const rat_point& b, const rat_point& c,
const rat_point& d)`
compares vectors $b-a$ and $d-c$ by angle (more efficient than calling `vector::compare_by_angle(b-a, d-x)` on `rat_vectors`).
- bool* `affinely_independent(const array<rat_point>& A)`
decides whether the points in A are affinely independent.
- bool* `contained_in_simplex(const array<rat_point>& A, const rat_point& p)`
determines whether p is contained in the simplex spanned by the points in A . A may consist of up to 3 points.
Precondition: The points in A are affinely independent.
- bool* `contained_in_affine_hull(const array<rat_point>& A, const rat_point& p)`
determines whether p is contained in the affine hull of the points in A .

15.11 Rational Segments (`rat_segment`)

1. Definition

An instance s of the data type `rat_segment` is a directed straight line segment in the two-dimensional plane, i.e., a line segment $[p, q]$ connecting two rational points p and q (cf. 15.10). p is called the *source* or start point and q is called the *target* or end point of s . A segment is called *trivial* if its source is equal to its target.

```
#include < LEDA/geo/rat_segment.h >
```

2. Types

`rat_segment::coord_type` the coordinate type (*rational*).

`rat_segment::point_type` the point type (*rat_point*).

`rat_segment::float_type` the corresponding floatin-point type (*segment*).

3. Creation

`rat_segment s;` introduces a variable s of type `rat_segment`. s is initialized to the empty segment.

`rat_segment s(const rat_point& p, const rat_point& q);`
introduces a variable s of type `rat_segment`. s is initialized to the segment $[p, q]$.

`rat_segment s(const rat_point& p, const rat_vector& v);`
introduces a variable s of type `rat_segment`. s is initialized to the segment $[p, p + v]$.
Precondition: $v.dim() = 2$.

`rat_segment s(const rational& x1, const rational& y1, const rational& x2,
 const rational& y2);`
introduces a variable s of type `rat_segment`. s is initialized to the segment $[(x1, y1), (x2, y2)]$.

`rat_segment s(const integer& x1, const integer& y1, const integer& w1,
 const integer& x2, const integer& y2, const integer& w2);`
introduces a variable s of type `rat_segment`. s is initialized to the segment $[(x1, y1, w1), (x2, y2, w2)]$.

`rat_segment s(const integer& x1, const integer& y1, const integer& x2,
 const integer& y2);`
introduces a variable s of type `rat_segment`. s is initialized to the segment $[(x1, y1), (x2, y2)]$.

rat_segment *s*(*const segment& s1*, *int prec = rat_point::default_precision*);

introduces a variable *s* of type *rat_segment*. *s* is initialized to the segment obtained by approximating the two defining points of *s1*.

4. Operations

<i>segment</i>	<i>s.to_float()</i>	returns a floating point approximation of <i>s</i> .
<i>void</i>	<i>s.normalize()</i>	simplifies the homogenous representation by calling <i>source().normalize()</i> and <i>target().normalize()</i> .
<i>rat_point</i>	<i>s.start()</i>	returns the source point of <i>s</i> .
<i>rat_point</i>	<i>s.end()</i>	returns the target point of <i>s</i> .
<i>rat_segment</i>	<i>s.reversal()</i>	returns the segment (<i>target()</i> , <i>source()</i>).
<i>rational</i>	<i>s.xcoord1()</i>	returns the <i>x</i> -coordinate of the source point of <i>s</i> .
<i>rational</i>	<i>s.xcoord2()</i>	returns the <i>x</i> -coordinate of the target point of <i>s</i> .
<i>rational</i>	<i>s.ycoord1()</i>	returns the <i>y</i> -coordinate of the source point of <i>s</i> .
<i>rational</i>	<i>s.ycoord2()</i>	returns the <i>y</i> -coordinate of the target point of <i>s</i> .
<i>double</i>	<i>s.xcoord1D()</i>	returns a double precision approximation of <i>s.xcoord1()</i> .
<i>double</i>	<i>s.xcoord2D()</i>	returns a double precision approximation of <i>s.xcoord2()</i> .
<i>double</i>	<i>s.ycoord1D()</i>	returns a double precision approximation of <i>s.ycoord1()</i> .
<i>double</i>	<i>s.ycoord2D()</i>	returns a double precision approximation of <i>s.ycoord2()</i> .
<i>integer</i>	<i>s.X1()</i>	returns the first homogeneous coordinate of the source point of <i>s</i> .
<i>integer</i>	<i>s.X2()</i>	returns the first homogeneous coordinate of the target point of <i>s</i> .
<i>integer</i>	<i>s.Y1()</i>	returns the second homogeneous coordinate of the source point of <i>s</i> .
<i>integer</i>	<i>s.Y2()</i>	returns the second homogeneous coordinate of the target point of <i>s</i> .
<i>integer</i>	<i>s.W1()</i>	returns the third homogeneous coordinate of the source point of <i>s</i> .

<i>integer</i>	<code>s.W2()</code>	returns the third homogeneous coordinate of the target point of s .
<i>double</i>	<code>s.XD1()</code>	returns a floating point approximation of $s.X1()$.
<i>double</i>	<code>s.XD2()</code>	returns a floating point approximation of $s.X2()$.
<i>double</i>	<code>s.YD1()</code>	returns a floating point approximation of $s.Y1()$.
<i>double</i>	<code>s.YD2()</code>	returns a floating point approximation of $s.Y2()$.
<i>double</i>	<code>s.WD1()</code>	returns a floating point approximation of $s.W1()$.
<i>double</i>	<code>s.WD2()</code>	returns a floating point approximation of $s.W2()$.
<i>integer</i>	<code>s.dx()</code>	returns the normalized x -difference $X2 \cdot W1 - X1 \cdot W2$ of s .
<i>integer</i>	<code>s.dy()</code>	returns the normalized y -difference $Y2 \cdot W1 - Y1 \cdot W2$ of s .
<i>double</i>	<code>s.dxD()</code>	returns a floating point approximation of $s.dx()$.
<i>double</i>	<code>s.dyD()</code>	returns a floating point approximation of $s.dy()$.
<i>bool</i>	<code>s.is_trivial()</code>	returns true if s is trivial.
<i>bool</i>	<code>s.is_vertical()</code>	returns true if s is vertical. <i>Precondition:</i> s is non-trivial.
<i>bool</i>	<code>s.is_horizontal()</code>	returns true if s is horizontal. <i>Precondition:</i> s is non-trivial.
<i>rational</i>	<code>s.slope()</code>	returns the slope of s . <i>Precondition:</i> s is not vertical.
<i>int</i>	<code>s.cmp_slope(const rat_segment& s1)</code>	compares the slopes of s and s_1 . <i>Precondition:</i> s and s_1 are non-trivial.
<i>int</i>	<code>s.orientation(const rat_point& p)</code>	computes $\text{orientation}(a, b, p)$ (see below), where $a \neq b$ and a and b appear in this order on segment s .
<i>rational</i>	<code>s.x_proj(rational y)</code>	returns $p.xcoord()$, where $p \in \text{line}(s)$ with $p.ycoord() = y$. <i>Precondition:</i> s is not horizontal.
<i>rational</i>	<code>s.y_proj(rational x)</code>	returns $p.ycoord()$, where $p \in \text{line}(s)$ with $p.xcoord() = x$. <i>Precondition:</i> s is not vertical.

- rational* *s.y_abs()* returns the y-*abscissa* of *line(s)*, i.e., *s.y_proj(0)*.
Precondition: *s* is not vertical.
- bool* *s.contains(const rat_point& p)*
 decides whether *s* contains *p*.
- bool* *s.intersection(const rat_segment& t)*
 decides whether *s* and *t* intersect.
- bool* *s.intersection(const rat_segment& t, rat_point& p)*
 decides whether *s* and *t* intersect. If so, some point of intersection is assigned to *p*.
- bool* *s.intersection(const rat_segment& t, rat_segment& inter)*
 decides whether *s* and *t* intersect. If so, the segment formed by the points of intersection is assigned to *inter*.
- bool* *s.intersection_of_lines(const rat_segment& t, rat_point& p)*
 decides if the lines supporting *s* and *t* intersect in a single point. If so, the point of intersection is assigned to *p*.
Precondition: *s* and *t* are nontrivial.
- bool* *s.overlaps(const rat_segment& t)*
 decides whether *s* and *t* overlap, i.e. they have a non-trivial intersection.
- rat_segment* *s.translate(const rational& dx, const rational& dy)*
 returns *s* translated by vector (dx, dy) .
- rat_segment* *s.translate(const integer& dx, const integer& dy, const integer& dw)*
 returns *s* translated by vector $(dx/dw, dy/dw)$.
- rat_segment* *s.translate(const rat_vector& v)*
 returns $s + v$, i.e., *s* translated by vector *v*.
Precondition: $v.dim() = 2$.
- rat_segment* $s + const\ rat_vector\&\ v$
 returns *s* translated by vector *v*.
- rat_segment* $s - const\ rat_vector\&\ v$
 returns *s* translated by vector $-v$.
- rat_segment* *s.rotate90(const rat_point& q, int i = 1)*
 returns *s* rotated about *q* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

- rat_segment* *s.rotate90(int i = 1)*
 returns *s* rotated about the origin by an angle of $i \times 90$ degrees.
- rat_segment* *s.reflect(const rat_point& p, const rat_point& q)*
 returns *s* reflected across the straight line passing through *p* and *q*.
- rat_segment* *s.reflect(const rat_point& p)*
 returns *s* reflected across point *p*.
- rat_segment* *s.reverse()* returns *s* reversed.
- rat_segment* *s.perpendicular(const rat_point& p)*
 returns the segment perpendicular to *s* with source *p* and target on *line(s)*.
Precondition: s is nontrivial.
- rational* *s.sqr_length()* returns the square of the length of *s*.
- rational* *s.sqr_dist(const rat_point& p)*
 returns the squared Euclidean distance between *p* and *s*.
- rational* *s.sqr_dist()* returns the squared distance between *s* and the origin.
- rat_vector* *s.to_vector()* returns the vector $s.target() - s.source()$.
- bool* *s == const rat_segment& t*
 returns true if *s* and *t* are equal as oriented segments
- int* *equal_as_sets(const rat_segment& s, const rat_segment& t)*
 returns true if *s* and *t* are equal as unoriented segments

Non-Member Functions

- int* *cmp_slopes(const rat_segment& s1, const rat_segment& s2)*
 returns $\text{compare}(\text{slope}(s_1), \text{slope}(s_2))$.
- int* *cmp_segments_at_xcoord(const rat_segment& s1, const rat_segment& s2, const rat_point& p)*
 compares points $l_1 \cap v$ and $l_2 \cap v$ where l_i is the line underlying segment s_i and v is the vertical straight line passing through point *p*.
- int* *orientation(const rat_segment& s, const rat_point& p)*
 computes $\text{orientation}(a, b, p)$, where $a \neq b$ and *a* and *b* appear in this order on segment *s*.

15.12 Rational Rays (rat_ray)

1. Definition

An instance r of the data type *rat_ray* is a directed straight ray defined by two points with rational coordinates in the two-dimensional plane.

```
#include < LEDA/geo/rat_ray.h >
```

2. Types

rat_ray::coord_type the coordinate type (*rational*).

rat_ray::point_type the point type (*rat_point*).

rat_ray::float_type the corresponding floatin-point type (*ray*).

3. Creation

```
rat_ray  $r$ (const rat_point&  $p$ , const rat_point&  $q$ );
```

introduces a variable r of type *rat_ray*. r is initialized to the ray starting at point p and passing through point q .

Precondition: $p \neq q$.

```
rat_ray  $r$ (const rat_segment&  $s$ );
```

introduces a variable r of type *rat_ray*. r is initialized to the (*rat_ray*($s.source()$, $s.target()$)).

Precondition: s is nontrivial.

```
rat_ray  $r$ (const rat_point&  $p$ , const rat_vector&  $v$ );
```

introduces a variable r of type *rat_ray*. r is initialized to *rat_ray*(p , $p + v$).

```
rat_ray  $r$ ;
```

introduces a variable r of type *rat_ray*.

```
rat_ray  $r$ (const ray&  $r_1$ , int  $prec = rat\_point::default\_precision$ );
```

introduces a variable r of type *rat_ray*. r is initialized to the ray obtained by approximating the two defining points of r_1 .

4. Operations

ray $r.to_float()$ returns a floating point approximation of r .

void $r.normalize()$ simplifies the homogenous representation by calling *point1*().*normalize*() and *point2*().*normlize*().

<i>rat_point</i>	<i>r</i> .source()	returns the source of <i>r</i> .
<i>rat_point</i>	<i>r</i> .point1()	returns the source of <i>r</i> .
<i>rat_point</i>	<i>r</i> .point2()	returns a point on <i>r</i> different from <i>r</i> .source().
<i>bool</i>	<i>r</i> .is_vertical()	returns true iff <i>r</i> is vertical.
<i>bool</i>	<i>r</i> .is_horizontal()	returns true iff <i>r</i> is horizontal.
<i>bool</i>	<i>r</i> .intersection(const <i>rat_ray</i> & <i>s</i> , <i>rat_point</i> & <i>inter</i>)	returns true if <i>r</i> and <i>s</i> intersect. If so, a point of intersection is returned in <i>inter</i> .
<i>bool</i>	<i>r</i> .intersection(const <i>rat_segment</i> & <i>s</i> , <i>rat_point</i> & <i>inter</i>)	returns true if <i>r</i> and <i>s</i> intersect. If so, a point of intersection is returned in <i>inter</i> .
<i>bool</i>	<i>r</i> .intersection(const <i>rat_segment</i> & <i>s</i>)	test if <i>r</i> and <i>s</i> intersect.
<i>rat_ray</i>	<i>r</i> .translate(const <i>rational</i> & <i>dx</i> , const <i>rational</i> & <i>dy</i>)	returns <i>r</i> translated by vector (<i>dx</i> , <i>dy</i>).
<i>rat_ray</i>	<i>r</i> .translate(<i>integer dx</i> , <i>integer dy</i> , <i>integer dw</i>)	returns <i>r</i> translated by vector (<i>dx/dw</i> , <i>dy/dw</i>).
<i>rat_ray</i>	<i>r</i> .translate(const <i>rat_vector</i> & <i>v</i>)	returns <i>r</i> + <i>v</i> , i.e., <i>r</i> translated by vector <i>v</i> . <i>Precondition: v.dim() = 2.</i>
<i>rat_ray</i>	<i>r</i> + const <i>rat_vector</i> & <i>v</i>	returns <i>r</i> translated by vector <i>v</i> .
<i>rat_ray</i>	<i>r</i> - const <i>rat_vector</i> & <i>v</i>	returns <i>r</i> translated by vector $-v$.
<i>rat_ray</i>	<i>r</i> .rotate90(const <i>rat_point</i> & <i>q</i> , int <i>i</i> = 1)	returns <i>r</i> rotated about <i>q</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
<i>rat_ray</i>	<i>r</i> .reflect(const <i>rat_point</i> & <i>p</i> , const <i>rat_point</i> & <i>q</i>)	returns <i>r</i> reflected across the straight line passing through <i>p</i> and <i>q</i> . <i>Precondition: p ≠ q.</i>
<i>rat_ray</i>	<i>r</i> .reflect(const <i>rat_point</i> & <i>p</i>)	returns <i>r</i> reflected across point <i>p</i> .
<i>rat_ray</i>	<i>r</i> .reverse()	returns <i>r</i> reversed.

15.13 Straight Rational Lines (`rat_line`)

1. Definition

An instance l of the data type `rat_line` is a directed straight line in the two-dimensional plane.

```
#include < LEDA/geo/rat_line.h >
```

2. Types

`rat_line::coord_type` the coordinate type (*rational*).

`rat_line::point_type` the point type (*rat_point*).

`rat_line::float_type` the corresponding float-in-point type (*line*).

3. Creation

```
rat_line  $l$ (const rat_point&  $p$ , const rat_point&  $q$ );
```

introduces a variable l of type `rat_line`. l is initialized to the line passing through points p and q directed from p to q .

Precondition: $p \neq q$.

```
rat_line  $l$ (const rat_segment&  $s$ );
```

introduces a variable l of type `rat_line`. l is initialized to the line supporting segment s .

Precondition: s is nontrivial.

```
rat_line  $l$ (const rat_point&  $p$ , const rat_vector&  $v$ );
```

introduces a variable l of type `rat_line`. l is initialized to the line passing through points p and $p + v$.

Precondition: v is a nonzero vector.

```
rat_line  $l$ (const rat_ray&  $r$ );
```

introduces a variable l of type `rat_line`. l is initialized to the line supporting ray r .

```
rat_line  $l$ ;
```

introduces a variable l of type `rat_line`.

```
rat_line  $l$ (const line&  $l_1$ , int prec = rat_point::default_precision);
```

introduces a variable l of type `rat_line`. l is initialized to the line obtained by approximating the two defining points of l_1 .

4. Operations

`line` `l.to_float()` returns a floating point approximation of l .

<i>void</i>	<i>l.normalize()</i>	simplifies the homogenous representation by calling <i>point1().normalize()</i> and <i>point2().normlize()</i> .
<i>rat_point</i>	<i>l.point1()</i>	returns a point on <i>l</i> .
<i>rat_point</i>	<i>l.point2()</i>	returns a second point on <i>l</i> .
<i>rat_segment</i>	<i>l.seg()</i>	returns a segment on <i>l</i> .
<i>bool</i>	<i>l.is_vertical()</i>	decides whether <i>l</i> is vertical.
<i>bool</i>	<i>l.is_horizontal()</i>	decides whether <i>l</i> is horizontal.
<i>rational</i>	<i>l.slope()</i>	returns the slope of <i>s</i> . <i>Precondition: l</i> is not vertical.
<i>rational</i>	<i>l.x_proj(rational y)</i>	returns <i>p.xcoord()</i> , where $p \in \text{line}(l)$ with $p.ycoord() = y$. <i>Precondition: l</i> is not horizontal.
<i>rational</i>	<i>l.y_proj(rational x)</i>	returns <i>p.ycoord()</i> , where $p \in \text{line}(l)$ with $p.xcoord() = x$. <i>Precondition: l</i> is not vertical.
<i>rational</i>	<i>l.y_abs()</i>	returns the y-abcissa of $\text{line}(l)$, i.e., <i>l.y_proj(0)</i> . <i>Precondition: l</i> is not vertical.
<i>bool</i>	<i>l.intersection(const rat_line& g, rat_point& inter)</i>	returns true if <i>l</i> and <i>g</i> intersect. In case of intersection a common point is returned in <i>inter</i> .
<i>bool</i>	<i>l.intersection(const rat_segment& s, rat_point& inter)</i>	returns true if <i>l</i> and <i>s</i> intersect. In case of intersection a common point is returned in <i>inter</i> .
<i>bool</i>	<i>l.intersection(const rat_segment& s)</i>	returns <i>true</i> , if <i>l</i> and <i>s</i> intersect, <i>false</i> otherwise.
<i>rat_line</i>	<i>l.translate(const rational& dx, const rational& dy)</i>	returns <i>l</i> translated by vector (dx, dy) .
<i>rat_line</i>	<i>l.translate(integer dx, integer dy, integer dw)</i>	returns <i>l</i> translated by vector $(dx/dw, dy/dw)$.
<i>rat_line</i>	<i>l.translate(const rat_vector& v)</i>	returns <i>l</i> translated by vector <i>v</i> . <i>Precondition: v.dim() = 2.</i>
<i>rat_line</i>	<i>l + const rat_vector& v</i>	returns <i>l</i> translated by vector <i>v</i> .

bool `equal_as_sets(const rat_line& l, const rat_line& g)`
returns true if the *l* and *g* are equal as unoriented lines.

Non-Member Functions

int `orientation(const rat_line& l, const rat_point& p)`
computes `orientation(a, b, p)`, where $a \neq b$ and *a* and *b* appear in this order on line *l*.

int `cmp_slopes(const rat_line& l1, const rat_line& l2)`
returns `compare(slope(l1), slope(l2))`.

rat_line `p_bisector(const rat_point& p, const rat_point& q)`
returns the perpendicular bisector of *p* and *q*. The bisector has *p* on its left.
Precondition: p ≠ q.

15.14 Rational Circles (`rat_circle`)

1. Definition

An instance C of data type `rat_circle` is an oriented circle in the plane. A circle is defined by three points p_1, p_2, p_3 with rational coordinates (*rat_points*). The orientation of C is equal to the orientation of the three defining points, i.e., $orientation(p_1, p_2, p_3)$. Positive orientation corresponds to counter-clockwise orientation and negative orientation corresponds to clockwise orientation.

Some triples of points are unsuitable for defining a circle. A triple is *admissible* if $|\{p_1, p_2, p_3\}| \neq 2$. Assume now that p_1, p_2, p_3 are admissible. If $|\{p_1, p_2, p_3\}| = 1$ they define the circle with center p_1 and radius zero. If p_1, p_2 , and p_3 are collinear C is a straight line passing through p_1, p_2 and p_3 in this order and the center of C is undefined. If p_1, p_2 , and p_3 are not collinear, C is the circle passing through them.

```
#include < LEDA/geo/rat_circle.h >
```

2. Types

`rat_circle::coord_type` the coordinate type (*rational*).

`rat_circle::point_type` the point type (*rat_point*).

`rat_circle::float_type` the corresponding floatin-point type (*circle*).

3. Creation

```
rat_circle C(const rat_point& a, const rat_point& b, const rat_point& c);
```

introduces a variable C of type `rat_circle`. C is initialized to the circle through points a, b , and c .

Precondition: a, b , and c are admissible.

```
rat_circle C(const rat_point& a, const rat_point& b);
```

introduces a variable C of type `circle`. C is initialized to the counter-clockwise oriented circle with center a passing through b .

```
rat_circle C(const rat_point& a);
```

introduces a variable C of type `circle`. C is initialized to the trivial circle with center a .

```
rat_circle C;
```

introduces a variable C of type `rat_circle`. C is initialized to the trivial circle centered at $(0, 0)$.

rat_circle $C(\text{const circle\& } c, \text{int } prec = \text{rat_point::default_precision});$

introduces a variable C of type *rat_circle*. C is initialized to the circle obtained by approximating three defining points of c .

4. Operations

<i>circle</i>	$C.\text{to_float}()$	returns a floating point approximation of C .
<i>void</i>	$C.\text{normalize}()$	simplifies the homogenous representation by normalizing p_1 , p_2 , and p_3 .
<i>int</i>	$C.\text{orientation}()$	returns the orientation of C .
<i>rat_point</i>	$C.\text{center}()$	returns the center of C . <i>Precondition:</i> C has a center, i.e., is not a line.
<i>rat_point</i>	$C.\text{point1}()$	returns p_1 .
<i>rat_point</i>	$C.\text{point2}()$	returns p_2 .
<i>rat_point</i>	$C.\text{point3}()$	returns p_3 .
<i>rational</i>	$C.\text{sq_radius}()$	returns the square of the radius of C .
<i>rat_point</i>	$C.\text{point_on_circle}(\text{double } \alpha, \text{double } \epsilon)$	returns a point p on C such that the angle of p differs from α by at most ϵ .
<i>bool</i>	$C.\text{is_degenerate}()$	returns true if the defining points are collinear.
<i>bool</i>	$C.\text{is_trivial}()$	returns true if C has radius zero.
<i>bool</i>	$C.\text{is_line}()$	returns true if C is a line.
<i>rat_line</i>	$C.\text{to_line}()$	returns $\text{line}(\text{point1}(), \text{point3}())$.
<i>int</i>	$C.\text{side_of}(\text{const } \text{rat_point\& } p)$	returns -1 , $+1$, or 0 if p lies right of, left of, or on C respectively.
<i>bool</i>	$C.\text{inside}(\text{const } \text{rat_point\& } p)$	returns true iff p lies inside of C .
<i>bool</i>	$C.\text{outside}(\text{const } \text{rat_point\& } p)$	returns true iff p lies outside of C .
<i>bool</i>	$C.\text{contains}(\text{const } \text{rat_point\& } p)$	returns true iff p lies on C .

- rat_circle* `C.translate(const rational& dx, const rational& dy)`
returns *C* translated by vector (dx, dy) .
- rat_circle* `C.translate(integer dx, integer dy, integer dw)`
returns *C* translated by vector $(dx/dw, dy/dw)$.
- rat_circle* `C.translate(const rat_vector& v)`
returns *C* translated by vector *v*.
- rat_circle* `C + const rat_vector& v` returns *C* translated by vector *v*.
- rat_circle* `C - const rat_vector& v` returns *C* translated by vector $-v$.
- rat_circle* `C.rotate90(const rat_point& q, int i = 1)`
returns *C* rotated by $i \times 90$ degrees about *q*. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- rat_circle* `C.reflect(const rat_point& p, const rat_point& q)`
returns *C* reflected across the straight line passing through *p* and *q*.
- rat_circle* `C.reflect(const rat_point& p)`
returns *C* reflected across point *p*.
- rat_circle* `C.reverse()` returns *C* reversed.
- bool* `C == const rat_circle& D` returns true if *C* and *D* are equal as oriented circles.
- bool* `equal_as_sets(const rat_circle& C1, const rat_circle& C2)`
returns true if *C1* and *C2* are equal as unoriented circles.
- bool* `radical_axis(const rat_circle& C1, const rat_circle& C2, rat_line& rad_axis)`
if the radical axis for *C1* and *C2* exists, it is assigned to *rad_axis* and true is returned; otherwise the result is false.
- ostream&* `ostream& out << const rat_circle& c`
writes the three defining points.
- istream&* `istream& in >> rat_circle& c`
reads three points and assigns the circle defined by them to *c*.

15.15 Rational Triangles (`rat_triangle`)

1. Definition

An instance t of the data type *rat_triangle* is an oriented triangle in the two-dimensional plane with rational coordinates. A *rat_triangle* t splits the plane into one bounded and one unbounded region. If t is positively oriented, the bounded region is to the left of it, if it is negatively oriented, the unbounded region is to the left of it. t is called degenerate, if the 3 vertices of t are collinear.

```
#include < LEDA/geo/rat_triangle.h >
```

2. Types

rat_triangle::*coord_type* the coordinate type (*rational*).

rat_triangle::*point_type* the point type (*rat_point*).

3. Creation

rat_triangle t ; introduces a variable t of type *rat_triangle*. t is initialized to the empty triangle.

rat_triangle $t(\text{const } \textit{rat_point}\& p, \text{const } \textit{rat_point}\& q, \text{const } \textit{rat_point}\& r)$; introduces a variable t of type *rat_triangle*. t is initialized to the triangle $[p, q, r]$.

rat_triangle $t(\text{const } \textit{rational}\& x1, \text{const } \textit{rational}\& y1, \text{const } \textit{rational}\& x2, \text{const } \textit{rational}\& y2, \text{const } \textit{rational}\& x3, \text{const } \textit{rational}\& y3)$; introduces a variable t of type *rat_triangle*. t is initialized to the triangle $[(x1, y1), (x2, y2), (x3, y3)]$.

rat_triangle $t(\text{const } \textit{triangle}\& t, \text{int } \textit{prec} = \textit{rat_point}::\textit{default_precision})$; introduces a variable t of type *rat_triangle*. t is initialized to the triangle obtained by approximating the three defining points of t .

4. Operations

void $t.\textit{normalize}()$ simplifies the homogenous representation by calling $p.\textit{normalize}()$ for every vertex of t .

rat_point $t.\textit{point1}()$ returns the first vertex of triangle t .

rat_point $t.\textit{point2}()$ returns the second vertex of triangle t .

rat_point $t.\textit{point3}()$ returns the third vertex of triangle t .

- rat_point* $t[int\ i]$ returns the i -th vertex of t . *Precondition:* $1 \leq i \leq 3$.
- int* $t.orientation()$ returns the orientation of t .
- rational* $t.area()$ returns the signed area of t (positive, if $orientation(a, b, c) > 0$, negative otherwise).
- bool* $t.is_degenerate()$ returns true if the vertices of t are collinear.
- int* $t.side_of(const\ rat_point\&\ p)$
returns +1 if p lies to the left of t , 0 if p lies on t and -1 if p lies to the right of t .
- region_kind* $t.region_of(const\ rat_point\&\ p)$
returns *BOUNDED_REGION* if p lies in the bounded region of t , *ON_REGION* if p lies on t and *UNBOUNDED_REGION* if p lies in the unbounded region.
- bool* $t.inside(const\ rat_point\&\ p)$
returns true, if p lies to the left of t .
- bool* $t.outside(const\ rat_point\&\ p)$
returns true, if p lies to the right of t .
- bool* $t.on_boundary(const\ rat_point\&\ p)$
decides whether p lies on the boundary of t .
- bool* $t.contains(const\ rat_point\&\ p)$
decides whether t contains p .
- bool* $t.intersection(const\ rat_line\&\ l)$
decides whether the bounded region or the boundary of t and l intersect.
- bool* $t.intersection(const\ rat_segment\&\ s)$
decides whether the bounded region or the boundary of t and s intersect.
- rat_triangle* $t.translate(rational\ dx, rational\ dy)$
returns t translated by vector (dx, dy) .
- rat_triangle* $t.translate(const\ rat_vector\&\ v)$
returns $t + v$, i.e., t translated by vector v .
Precondition: $v.dim() = 2$.
- rat_triangle* $t + const\ rat_vector\&\ v$
returns t translated by vector v .

rat_triangle *t* – *const rat_vector&* *v*

returns *t* translated by vector $-v$.

rat_triangle *t*.rotate90(*const rat_point&* *q*, *int* *i* = 1)

returns *t* rotated about *q* by an angle of $i \times 90$ degrees.
If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

rat_triangle *t*.rotate90(*int* *i* = 1)

returns *t*.rotate90(*t*.source(),*i*).

rat_triangle *t*.reflect(*const rat_point&* *p*, *const rat_point&* *q*)

returns *t* reflected across the straight line passing through *p* and *q*.

rat_triangle *t*.reflect(*const rat_point&* *p*)

returns *t* reflected across point *p*.

rat_triangle *t*.reverse()

returns *t* reversed.

15.16 Iso-oriented Rational Rectangles (`rat_rectangle`)

1. Definition

An instance r of the data type *rectangle* is an iso-oriented rectangle in the two-dimensional plane with rational coordinates.

```
#include < LEDA/geo/rat_rectangle.h >
```

2. Creation

```
rat_rectangle r(const rat_point& p, const rat_point& q);
```

introduces a variable r of type *rat_rectangle*. r is initialized to the *rat_rectangle* with diagonal corners p and q

```
rat_rectangle r(const rat_point& p, rational w, rational h);
```

introduces a variable r of type *rat_rectangle*. r is initialized to the *rat_rectangle* with lower left corner p , width w and height h .

```
rat_rectangle r(rational x1, rational y1, rational x2, rational y2);
```

introduces a variable r of type *rat_rectangle*. r is initialized to the *rat_rectangle* with diagonal corners $(x1, y1)$ and $(x2, y2)$.

```
rat_rectangle r(const rectangle& r, int prec = rat_point::default_precision);
```

introduces a variable r of type *rat_rectangle*. r is initialized to the rectangle obtained by approximating the defining points of r .

3. Operations

```
rectangle r.to_float() returns a floating point approximation of  $R$ .
```

```
void r.normalize() simplifies the homogenous representation by calling  $p.normalize()$  for every vertex of  $r$ .
```

```
rat_point r.upper_left() returns the upper left corner.
```

```
rat_point r.upper_right() returns the upper right corner.
```

```
rat_point r.lower_left() returns the lower left corner.
```

```
rat_point r.lower_right() returns the lower right corner.
```

```
rat_point r.center() returns the center of  $r$ .
```

<i>list<rat_point></i>	<i>r.vertices()</i>	returns the vertices of <i>r</i> in counter-clockwise order starting from the lower left point.
<i>rational</i>	<i>r.xmin()</i>	returns the minimal x-coordinate of <i>r</i> .
<i>rational</i>	<i>r.xmax()</i>	returns the maximal x-coordinate of <i>r</i> .
<i>rational</i>	<i>r.ymin()</i>	returns the minimal y-coordinate of <i>r</i> .
<i>rational</i>	<i>r.ymax()</i>	returns the maximal y-coordinate of <i>r</i> .
<i>rational</i>	<i>r.width()</i>	returns the width of <i>r</i> .
<i>rational</i>	<i>r.height()</i>	returns the height of <i>r</i> .
<i>bool</i>	<i>r.is_degenerate()</i>	returns true, if <i>r</i> degenerates to a segment or point (the 4 corners are collinear), false otherwise.
<i>bool</i>	<i>r.is_point()</i>	returns true, if <i>r</i> degenerates to a point.
<i>bool</i>	<i>r.is_segment()</i>	returns true, if <i>r</i> degenerates to a segment.
<i>int</i>	<i>r.cs_code(const rat_point& p)</i>	returns the code for Cohen-Sutherland algorithm.
<i>bool</i>	<i>r.inside(const rat_point& p)</i>	returns true, if <i>p</i> is inside of <i>r</i> , false otherwise.
<i>bool</i>	<i>r.inside_or_contains(const rat_point& p)</i>	returns true, if <i>p</i> is inside of <i>r</i> or on the border, false otherwise.
<i>bool</i>	<i>r.outside(const rat_point& p)</i>	returns true, if <i>p</i> is outside of <i>r</i> , false otherwise.
<i>bool</i>	<i>r.contains(const rat_point& p)</i>	returns true, if <i>p</i> is on the border of <i>r</i> , false otherwise.
<i>region_kind</i>	<i>r.region_of(const rat_point& p)</i>	returns BOUNDED_REGION if <i>p</i> lies in the bounded region of <i>r</i> , returns ON_REGION if <i>p</i> lies on <i>r</i> , and returns UNBOUNDED_REGION if <i>p</i> lies in the unbounded region.
<i>rat_rectangle</i>	<i>r.include(const rat_point& p)</i>	returns a new <i>rat_rectangle</i> that includes the points of <i>r</i> and <i>p</i> .

rat_rectangle *r*.include(*const rat_rectangle& r2*)

returns a new *rat_rectangle* that includes the points of *r* and *r2*.

rat_rectangle *r*.translate(*rational dx, rational dy*)

returns *r* translated by (dx, dy) .

rat_rectangle *r*.translate(*const rat_vector& v*)

returns *r* translated by *v*.

rat_rectangle *r* + *const rat_vector& v* returns *r* translated by *v*.

rat_rectangle *r* - *const rat_vector& v* returns *r* translated by vector $-v$.

rat_point *r*[*int i*]

returns the *i* - *th* vertex of *r*. Precondition: $(0 < i < 5)$.

rat_rectangle *r*.rotate90(*const rat_point& p, int i = 1*)

returns *r* rotated about *q* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

rat_rectangle *r*.rotate90(*int i = 1*)

returns *r* rotated by an angle of $i \times 90$ degrees about the origin.

rat_rectangle *r*.reflect(*const rat_point& p*)

returns *r* reflected across *p*.

bool *r*.clip(*const rat_segment& t, rat_segment& inter*)

clips *t* on *r* and returns the result in *inter*.

bool *r*.clip(*const rat_line& l, rat_segment& inter*)

clips *l* on *r* and returns the result in *inter*.

bool *r*.clip(*const rat_ray& ry, rat_segment& inter*)

clips *ry* on *r* and returns the result in *inter*.

bool *r*.difference(*const rat_rectangle& q, list<rat_rectangle>& L*)

returns *true* iff the difference of *r* and *q* is not empty, and *false* otherwise. The difference *L* is returned as a partition into rectangles.

list<rat_point> *r*.intersection(*const rat_segment& s*)

returns $r \cap s$.

list<rat_point> *r*.intersection(*const rat_line& l*)

returns $r \cap l$.

list<rat_rectangle> *r.intersection(const rat_rectangle& s)*

returns $r \cap s$.

bool *r.do_intersect(const rat_rectangle& b)*

returns *true* iff *r* and *b* intersect, false otherwise.

rational *r.area()*

returns the area of *r*.

- int* `p.orientation(const real_point& q, const real_point& r)`
returns *orientation*(*p*, *q*, *r*) (see below).
- real* `p.area(const real_point& q, const real_point& r)`
returns *area*(*p*, *q*, *r*) (see below).
- real* `p.sqr_dist(const real_point& q)`
returns the square of the Euclidean distance between *p* and *q*.
- int* `p.cmp_dist(const real_point& q, const real_point& r)`
returns *compare*(*p.sqr_dist*(*q*), *p.sqr_dist*(*r*)).
- real* `p.xdist(const real_point& q)`
returns the horizontal distance between *p* and *q*.
- real* `p.ydist(const real_point& q)`
returns the vertical distance between *p* and *q*.
- real* `p.distance(const real_point& q)`
returns the Euclidean distance between *p* and *q*.
- real* `p.distance()` returns the Euclidean distance between *p* and (0, 0).
- real_point* `p.translate(real dx, real dy)`
returns *p* translated by vector (*dx*, *dy*).
- real_point* `p.translate(double dx, double dy)`
returns *p* translated by vector (*dx*, *dy*).
- real_point* `p.translate(const real_vector& v)`
returns *p+v*, i.e., *p* translated by vector *v*.
Precondition: *v.dim*() = 2.
- real_point* `p + const real_vector& v`
returns *p* translated by vector *v*.
- real_point* `p - const real_vector& v`
returns *p* translated by vector $-v$.
- real_point* `p.rotate90(const real_point& q, int i = 1)`
returns *p* rotated about *q* by an angle of $i \times 90$ degrees.
If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- real_point* `p.rotate90(int i = 1)` returns *p.rotate90*(*real_point*(0, 0), *i*).

real_point `p.reflect(const real_point& q, const real_point& r)`

returns p reflected across the straight line passing through q and r .

real_point `p.reflect(const real_point& q)`

returns p reflected across point q .

real_vector `p - const real_point& q`

returns the difference vector of the coordinates.

Non-Member Functions

int `cmp_distances(const real_point& p1, const real_point& p2,
const real_point& p3, const real_point& p4)`

compares the distances $(p1, p2)$ and $(p3, p4)$. Returns +1 (−1) if distance $(p1, p2)$ is larger (smaller) than distance $(p3, p4)$, otherwise 0.

real_point `center(const real_point& a, const real_point& b)`

returns the center of a and b , i.e. $a + \vec{ab}/2$.

real_point `midpoint(const real_point& a, const real_point& b)`

returns the center of a and b .

int `orientation(const real_point& a, const real_point& b, const real_point& c)`

computes the orientation of points a , b , and c as the sign of the determinant

$$\begin{vmatrix} a_x & a_y & 1 \\ b_x & b_y & 1 \\ c_x & c_y & 1 \end{vmatrix}$$

i.e., it returns +1 if point c lies left of the directed line through a and b , 0 if a, b , and c are collinear, and −1 otherwise.

int `cmp_signed_dist(const real_point& a, const real_point& b, const real_point& c,
const real_point& d)`

compares (signed) distances of c and d to the straight line passing through a and b (directed from a to b). Returns +1 (−1) if c has larger (smaller) distance than d and 0 if distances are equal.

- real* `area(const real_point& a, const real_point& b, const real_point& c)`
 computes the signed area of the triangle determined by a, b, c , positive if $orientation(a, b, c) > 0$ and negative otherwise.
- bool* `collinear(const real_point& a, const real_point& b, const real_point& c)`
 returns *true* if points a, b, c are collinear, i.e., $orientation(a, b, c) = 0$, and *false* otherwise.
- bool* `right_turn(const real_point& a, const real_point& b, const real_point& c)`
 returns *true* if points a, b, c form a right turn, i.e., $orientation(a, b, c) < 0$, and *false* otherwise.
- bool* `left_turn(const real_point& a, const real_point& b, const real_point& c)`
 returns *true* if points a, b, c form a left turn, i.e., $orientation(a, b, c) > 0$, and *false* otherwise.
- int* `side_of_halfspace(const real_point& a, const real_point& b, const real_point& c)`
 returns the sign of the scalar product $(b - a) \cdot (c - a)$. If $b \neq a$ this amounts to: Let h be the open halfspace orthogonal to the vector $b - a$, containing b , and having a in its boundary. Returns $+1$ if c is contained in h , returns 0 if c lies on the boundary of h , and returns -1 if c is contained in the interior of the complement of h .
- int* `side_of_circle(const real_point& a, const real_point& b, const real_point& c,
 const real_point& d)`
 returns $+1$ if point d lies left of the directed circle through points a, b , and c , 0 if a, b, c , and d are cocircular, and -1 otherwise.
- bool* `inside_circle(const real_point& a, const real_point& b, const real_point& c,
 const real_point& d)`
 returns *true* if point d lies in the interior of the circle through points a, b , and c , and *false* otherwise.
- bool* `outside_circle(const real_point& a, const real_point& b, const real_point& c,
 const real_point& d)`
 returns *true* if point d lies outside of the circle through points a, b , and c , and *false* otherwise.
- bool* `on_circle(const real_point& a, const real_point& b, const real_point& c,
 const real_point& d)`
 returns *true* if points a, b, c , and d are cocircular.
- bool* `cocircular(const real_point& a, const real_point& b, const real_point& c,
 const real_point& d)`
 returns *true* if points a, b, c , and d are cocircular.

- int* `compare_by_angle(const real_point& a, const real_point& b,
 const real_point& c, const real_point& d)`
 compares vectors $b - a$ and $d - c$ by angle (more efficient
 than calling `compare_by_angle(b - a, d - x)` on vectors).
- bool* `affinely_independent(const array<real_point>& A)`
 decides whether the points in A are affinely independent.
- bool* `contained_in_simplex(const array<real_point>& A, const real_point& p)`
 determines whether p is contained in the simplex
 spanned by the points in A . A may consist of up to
 3 points.
 Precondition: The points in A are affinely independent.
- bool* `contained_in_affine_hull(const array<real_point>& A, const real_point& p)`
 determines whether p is contained in the affine hull of
 the points in A .

15.18 Real Segments (*real_segment*)

1. Definition

An instance s of the data type *real_segment* is a directed straight line segment in the two-dimensional plane, i.e., a straight line segment $[p, q]$ connecting two points $p, q \in \mathbb{R}^2$. p is called the *source* or start point and q is called the *target* or end point of s . The length of s is the Euclidean distance between p and q . If $p = q$, s is called empty. We use *line*(s) to denote a straight line containing s .

```
#include < LEDA/geo/real_segment.h >
```

2. Types

real_segment::*coord_type* the coordinate type (*real*).

real_segment::*point_type* the point type (*real_point*).

3. Creation

```
real_segment s(const real_point& p, const real_point& q);
```

introduces a variable s of type *real_segment*. s is initialized to the segment $[p, q]$.

```
real_segment s(const real_point& p, const real_vector& v);
```

introduces a variable s of type *real_segment*. s is initialized to the segment $[p, p + v]$.

Precondition: $v.dim() = 2$.

```
real_segment s(real x1, real y1, real x2, real y2);
```

introduces a variable s of type *real_segment*. s is initialized to the segment $[(x_1, y_1), (x_2, y_2)]$.

```
real_segment s;
```

introduces a variable s of type *real_segment*. s is initialized to the empty segment.

```
real_segment s(const segment& s1, int prec = 0);
```

introduces a variable s of type *real_segment* initialized to the segment s_1 . (The second argument is for compatibility with *rat_segment*.)

```
real_segment s(const rat_segment& s1);
```

introduces a variable s of type *real_segment* initialized to the segment s_1 .

4. Operations

<i>real_point</i>	<i>s.start()</i>	returns the source point of segment <i>s</i> .
<i>real_point</i>	<i>s.end()</i>	returns the target point of segment <i>s</i> .
<i>real</i>	<i>s.xcoord1()</i>	returns the x-coordinate of <i>s.source()</i> .
<i>real</i>	<i>s.xcoord2()</i>	returns the x-coordinate of <i>s.target()</i> .
<i>real</i>	<i>s.ycoord1()</i>	returns the y-coordinate of <i>s.source()</i> .
<i>real</i>	<i>s.ycoord2()</i>	returns the y-coordinate of <i>s.target()</i> .
<i>real</i>	<i>s.dx()</i>	returns the $xcoord2 - xcoord1$.
<i>real</i>	<i>s.dy()</i>	returns the $ycoord2 - ycoord1$.
<i>real</i>	<i>s.slope()</i>	returns the slope of <i>s</i> . <i>Precondition: s</i> is not vertical.
<i>real</i>	<i>s.sqr_length()</i>	returns the square of the length of <i>s</i> .
<i>real</i>	<i>s.length()</i>	returns the length of <i>s</i> .
<i>real_vector</i>	<i>s.to_vector()</i>	returns the vector $s.target() - s.source()$.
<i>bool</i>	<i>s.is_trivial()</i>	returns true if <i>s</i> is trivial.
<i>bool</i>	<i>s.is_vertical()</i>	returns true iff <i>s</i> is vertical.
<i>bool</i>	<i>s.is_horizontal()</i>	returns true iff <i>s</i> is horizontal.
<i>int</i>	<i>s.orientation(const real_point& p)</i>	computes $orientation(s.source(), s.target(), p)$ (see below).
<i>real</i>	<i>s.x_proj(real y)</i>	returns $p.xcoord()$, where $p \in line(s)$ with $p.ycoord() = y$. <i>Precondition: s</i> is not horizontal.
<i>real</i>	<i>s.y_proj(real x)</i>	returns $p.ycoord()$, where $p \in line(s)$ with $p.xcoord() = x$. <i>Precondition: s</i> is not vertical.
<i>real</i>	<i>s.y_abs()</i>	returns the y-abscissa of $line(s)$, i.e., $s.y_proj(0)$. <i>Precondition: s</i> is not vertical.
<i>bool</i>	<i>s.contains(const real_point& p)</i>	decides whether <i>s</i> contains <i>p</i> .
<i>bool</i>	<i>s.intersection(const real_segment& t)</i>	decides whether <i>s</i> and <i>t</i> intersect in one point.

- bool* `s.intersection(const real_segment& t, real_point& p)`
 if s and t intersect in a single point this point is assigned to p and the result is true, otherwise the result is false.
- bool* `s.intersection_of_lines(const real_segment& t, real_point& p)`
 if $line(s)$ and $line(t)$ intersect in a single point this point is assigned to p and the result is true, otherwise the result is false.
- real_segment* `s.translate(real dx, real dy)`
 returns s translated by vector (dx, dy) .
- real_segment* `s.translate(const real_vector& v)`
 returns $s + v$, i.e., s translated by vector v .
Precondition: $v.dim() = 2$.
- real_segment* `s + const real_vector& v`
 returns s translated by vector v .
- real_segment* `s - const real_vector& v`
 returns s translated by vector $-v$.
- real_segment* `s.perpendicular(const real_point& p)`
 returns the segment perpendicular to s with source p and target on $line(s)$.
- real* `s.distance(const real_point& p)`
 returns the Euclidean distance between p and s .
- real* `s.sqr_dist(const real_point& p)`
 returns the squared Euclidean distance between p and s .
- real* `s.distance()` returns the Euclidean distance between $(0, 0)$ and s .
- real_segment* `s.rotate90(const real_point& q, int i = 1)`
 returns s rotated about q by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- real_segment* `s.rotate90(int i = 1)`
 returns $s.rotate90(s.source(), i)$.
- real_segment* `s.reflect(const real_point& p, const real_point& q)`
 returns s reflected across the straight line passing through p and q .
- real_segment* `s.reflect(const real_point& p)`
 returns s reflected across point p .

real_segment *s*.reverse() returns *s* reversed.

Non-Member Functions

int orientation(*const real_segment& s*, *const real_point& p*)
 computes orientation(*s.source()*, *s.target()*, *p*).

int cmp_slopes(*const real_segment& s1*, *const real_segment& s2*)
 returns compare(slope(*s1*), slope(*s2*)).

int cmp_segments_at_xcoord(*const real_segment& s1*, *const real_segment& s2*,
const real_point& p)
 compares points $l_1 \cap v$ and $l_2 \cap v$ where l_i is the line underlying segment s_i and v is the vertical straight line passing through point p .

bool parallel(*const real_segment& s1*, *const real_segment& s2*)
 returns true if $s1$ and $s2$ are parallel and false otherwise.

15.19 Real Rays (real_ray)

1. Definition

An instance r of the data type *real_ray* is a directed straight ray in the two-dimensional plane.

```
#include < LEDA/geo/real_ray.h >
```

2. Types

real_ray::coord_type the coordinate type (*real*).

real_ray::point_type the point type (*real_point*).

3. Creation

```
real_ray r(const real_point& p, const real_point& q);
```

introduces a variable r of type *real_ray*. r is initialized to the ray starting at point p and passing through point q .

```
real_ray r(const real_segment& s);
```

introduces a variable r of type *real_ray*. r is initialized to *real_ray*($s.source()$, $s.target()$).

```
real_ray r(const real_point& p, const real_vector& v);
```

introduces a variable r of type *real_ray*. r is initialized to *real_ray*(p , $p + v$).

```
real_ray r;
```

introduces a variable r of type *real_ray*. r is initialized to the ray starting at the origin with direction 0.

```
real_ray r(const ray& r1, int prec = 0);
```

introduces a variable r of type *real_ray* initialized to the ray r_1 . (The second argument is for compatibility with *rat_ray*.)

```
real_ray r(const rat_ray& r1);
```

introduces a variable r of type *real_ray* initialized to the ray r_1 .

4. Operations

real_point r.source() returns the source of r .

real_point r.point1() returns the source of r .

<i>real_point</i>	<i>r.point2()</i>	returns a point on <i>r</i> different from <i>r.source()</i> .
<i>bool</i>	<i>r.is_vertical()</i>	returns true iff <i>r</i> is vertical.
<i>bool</i>	<i>r.is_horizontal()</i>	returns true iff <i>r</i> is horizontal.
<i>real</i>	<i>r.slope()</i>	returns the slope of the straight line underlying <i>r</i> . <i>Precondition:</i> <i>r</i> is not vertical.
<i>bool</i>	<i>r.intersection(const real_ray& s, real_point& inter)</i>	if <i>r</i> and <i>s</i> intersect in a single point this point is assigned to <i>inter</i> and the result is <i>true</i> , otherwise the result is <i>false</i> .
<i>bool</i>	<i>r.intersection(const real_segment& s, real_point& inter)</i>	if <i>r</i> and <i>s</i> intersect in a single point this point is assigned to <i>inter</i> and the result is <i>true</i> , otherwise the result is <i>false</i> .
<i>real_ray</i>	<i>r.translate(real dx, real dy)</i>	returns <i>r</i> translated by vector (dx, dy) .
<i>real_ray</i>	<i>r.translate(const real_vector& v)</i>	returns <i>r</i> translated by vector <i>v</i> <i>Precondition:</i> $v.dim() = 2$.
<i>real_ray</i>	<i>r + const real_vector& v</i>	returns <i>r</i> translated by vector <i>v</i> .
<i>real_ray</i>	<i>r - const real_vector& v</i>	returns <i>r</i> translated by vector $-v$.
<i>real_ray</i>	<i>r.rotate90(const real_point& q, int i = 1)</i>	returns <i>r</i> rotated about <i>q</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
<i>real_ray</i>	<i>r.reflect(const real_point& p, const real_point& q)</i>	returns <i>r</i> reflected across the straight line passing through <i>p</i> and <i>q</i> .
<i>real_ray</i>	<i>r.reflect(const real_point& p)</i>	returns <i>r</i> reflected across point <i>p</i> .
<i>real_ray</i>	<i>r.reverse()</i>	returns <i>r</i> reversed.
<i>bool</i>	<i>r.contains(const real_point&)</i>	decides whether <i>r</i> contains <i>p</i> .
<i>bool</i>	<i>r.contains(const real_segment&)</i>	decides whether <i>r</i> contains <i>s</i> .

Non-Member Functions

int orientation(*const real_ray& r, const real_point& p*)

computes orientation(a, b, p) (see the manual page of *real_point*), where $a \neq b$ and a and b appear in this order on ray r .

int cmp_slopes(*const real_ray& r1, const real_ray& r2*)

returns compare(slope(r_1), slope(r_2)) where *slope*(r_i) denotes the slope of the straight line underlying r_i .

15.20 Straight Real Lines (`real_line`)

1. Definition

An instance l of the data type `real_line` is a directed straight line in the two-dimensional plane.

```
#include < LEDA/geo/real_line.h >
```

2. Types

`real_line::coord_type` the coordinate type (`real`).

`real_line::point_type` the point type (`real_point`).

3. Creation

```
real_line  $l$ (const real_point&  $p$ , const real_point&  $q$ );
```

introduces a variable l of type `real_line`. l is initialized to the line passing through points p and q directed from p to q .

```
real_line  $l$ (const real_segment&  $s$ );
```

introduces a variable l of type `real_line`. l is initialized to the line supporting segment s .

```
real_line  $l$ (const real_ray&  $r$ );
```

introduces a variable l of type `real_line`. l is initialized to the line supporting ray r .

```
real_line  $l$ (const real_point&  $p$ , const real_vector&  $v$ );
```

introduces a variable l of type `real_line`. l is initialized to the line passing through points p and $p + v$.

```
real_line  $l$ ;
```

introduces a variable l of type `real_line`. l is initialized to the line passing through the origin with direction 0.

```
real_line  $l$ (const line&  $l_1$ , int prec = 0);
```

introduces a variable l of type `real_line` initialized to the line l_1 . (The second argument is for compatibility with `rat_line`.)

```
real_line  $l$ (const rat_line&  $l_1$ );
```

introduces a variable l of type `real_line` initialized to the line l_1 .

4. Operations

<i>real_point</i>	<i>l.point1()</i>	returns a point on <i>l</i> .
<i>real_point</i>	<i>l.point2()</i>	returns a second point on <i>l</i> .
<i>real_segment</i>	<i>l.seg()</i>	returns a segment on <i>l</i> .
<i>bool</i>	<i>l.is_vertical()</i>	returns true iff <i>l</i> is vertical.
<i>bool</i>	<i>l.is_horizontal()</i>	returns true iff <i>l</i> is horizontal.
<i>real</i>	<i>l.sqr_dist(const real_point& q)</i>	returns the square of the distance between <i>l</i> and <i>q</i> .
<i>real</i>	<i>l.distance(const real_point& q)</i>	returns the distance between <i>l</i> and <i>q</i> .
<i>int</i>	<i>l.orientation(const real_point& p)</i>	returns <i>orientation(l.point1(), l.point2(), p)</i> .
<i>real</i>	<i>l.slope()</i>	returns the slope of <i>l</i> . <i>Precondition: l</i> is not vertical.
<i>real</i>	<i>l.y_proj(real x)</i>	returns <i>p.ycoord()</i> , where $p \in l$ with $p.xcoord() = x$. <i>Precondition: l</i> is not vertical.
<i>real</i>	<i>l.x_proj(real y)</i>	returns <i>p.xcoord()</i> , where $p \in l$ with $p.ycoord() = y$. <i>Precondition: l</i> is not horizontal.
<i>real</i>	<i>l.y_abs()</i>	returns the y-abscissa of <i>l</i> (<i>l.y_proj(0)</i>). <i>Precondition: l</i> is not vertical.
<i>bool</i>	<i>l.intersection(const real_line& g, real_point& p)</i>	if <i>l</i> and <i>g</i> intersect in a single point this point is assigned to <i>p</i> and the result is true, otherwise the result is false.
<i>bool</i>	<i>l.intersection(const real_segment& s, real_point& inter)</i>	if <i>l</i> and <i>s</i> intersect in a single point this point is assigned to <i>p</i> and the result is true, otherwise the result is false.
<i>bool</i>	<i>l.intersection(const real_segment& s)</i>	returns <i>true</i> , if <i>l</i> and <i>s</i> intersect, <i>false</i> otherwise.
<i>real_line</i>	<i>l.translate(real dx, real dy)</i>	returns <i>l</i> translated by vector (<i>dx</i> , <i>dy</i>).

- real_line* `l.translate(const real_vector& v)`
 returns l translated by vector v .
Precondition: $v.dim() = 2$.
- real_line* `l + const real_vector& v` returns l translated by vector v .
- real_line* `l - const real_vector& v` returns l translated by vector $-v$.
- real_line* `l.rotate90(const real_point& q, int i = 1)`
 returns l rotated about q by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- real_line* `l.reflect(const real_point& p, const real_point& q)`
 returns l reflected across the straight line passing through p and q .
- real_line* `l.reverse()` returns l reversed.
- real_segment* `l.perpendicular(const real_point& p)`
 returns the segment perpendicular to l with source p . and target on l .
- real_point* `l.dual()` returns the point dual to l .
Precondition: l is not vertical.
- int* `l.side_of(const real_point& p)`
 computes orientation(a, b, p), where $a \neq b$ and a and b appear in this order on line l .
- bool* `l.contains(const real_point& p)`
 returns true if p lies on l .
- bool* `l.clip(real_point p, real_point q, real_segment& s)`
 clips l at the rectangle R defined by p and q . Returns true if the intersection of R and l is non-empty and returns false otherwise. If the intersection is non-empty the intersection is assigned to s ; it is guaranteed that the source node of s is no larger than its target node.

Non-Member Functions

- int* `orientation(const real_line& l, const real_point& p)`
 computes orientation(a, b, p) (see the manual page of *real_point*), where $a \neq b$ and a and b appear in this order on line l .

int `cmp_slopes(const real_line& l1, const real_line& l2)`
 returns `compare(slope(l1), slope(l2))`.

15.21 Real Circles (`real_circle`)

1. Definition

An instance C of the data type *real_circle* is an oriented circle in the plane passing through three points p_1, p_2, p_3 . The orientation of C is equal to the orientation of the three defining points, i.e. $orientation(p_1, p_2, p_3)$. If $|\{p_1, p_2, p_3\}| = 1$ C is the empty circle with center p_1 . If p_1, p_2, p_3 are collinear C is a straight line passing through p_1, p_2 and p_3 in this order and the center of C is undefined.

```
#include < LEDA/geo/real_circle.h >
```

2. Types

real_circle::*coord_type* the coordinate type (*real*).

real_circle::*point_type* the point type (*real_point*).

3. Creation

```
real_circle C(const real_point& a, const real_point& b, const real_point& c);
```

introduces a variable C of type *real_circle*. C is initialized to the oriented circle through points a, b , and c .

```
real_circle C(const real_point& a, const real_point& b);
```

introduces a variable C of type *real_circle*. C is initialized to the counter-clockwise oriented circle with center a passing through b .

```
real_circle C(const real_point& a);
```

introduces a variable C of type *real_circle*. C is initialized to the trivial circle with center a .

```
real_circle C;
```

introduces a variable C of type *real_circle*. C is initialized to the trivial circle with center $(0, 0)$.

```
real_circle C(const real_point& c, real r);
```

introduces a variable C of type *real_circle*. C is initialized to the circle with center c and radius r with positive (i.e. counter-clockwise) orientation.

```
real_circle C(real x, real y, real r);
```

introduces a variable C of type *real_circle*. C is initialized to the circle with center (x, y) and radius r with positive (i.e. counter-clockwise) orientation.

real_circle $C(\text{const circle}\& c, \text{int } \text{prec} = 0);$

introduces a variable C of type *real_circle* initialized to the circle c . (The second argument is for compatibility with *rat_circle*.)

real_circle $C(\text{const rat_circle}\& c);$

introduces a variable C of type *real_circle* initialized to the circle c .

4. Operations

real_point $C.\text{center}();$

returns the center of C .

Precondition: The orientation of C is not 0.

real $C.\text{radius}();$

returns the radius of C .

Precondition: The orientation of C is not 0.

real $C.\text{sqr_radius}();$

returns the squared radius of C .

Precondition: The orientation of C is not 0.

real_point $C.\text{point1}();$

returns p_1 .

real_point $C.\text{point2}();$

returns p_2 .

real_point $C.\text{point3}();$

returns p_3 .

bool $C.\text{is_degenerate}();$

returns true if the defining points are collinear.

bool $C.\text{is_trivial}();$

returns true if C has radius zero.

bool $C.\text{is_line}();$

returns true if C is a line.

real_line $C.\text{to_line}();$

returns $\text{line}(\text{point1}(), \text{point3}())$.

int $C.\text{orientation}();$

returns the orientation of C .

int $C.\text{side_of}(\text{const } \text{real_point}\& p)$

returns -1 , $+1$, or 0 if p lies right of, left of, or on C respectively.

bool $C.\text{inside}(\text{const } \text{real_point}\& p)$

returns true iff p lies inside of C .

bool $C.\text{outside}(\text{const } \text{real_point}\& p)$

returns true iff p lies outside of C .

bool $C.\text{contains}(\text{const } \text{real_point}\& p)$

returns true iff p lies on C .

- real_circle* *C.translate(real dx, real dy)*
returns *C* translated by vector (dx, dy) .
- real_circle* *C.translate(const real_vector& v)*
returns *C* translated by vector *v*.
- real_circle* *C + const real_vector& v* returns *C* translated by vector *v*.
- real_circle* *C - const real_vector& v* returns *C* translated by vector $-v$.
- real_circle* *C.rotate90(const real_point& q, int i = 1)*
returns *C* rotated about *q* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- real_circle* *C.reflect(const real_point& p, const real_point& q)*
returns *C* reflected across the straight line passing through *p* and *q*.
- real_circle* *C.reflect(const real_point& p)*
returns *C* reflected across point *p*.
- real_circle* *C.reverse()* returns *C* reversed.
- list<real_point>* *C.intersection(const real_circle& D)*
returns $C \cap D$ as a list of points.
- list<real_point>* *C.intersection(const real_line& l)*
returns $C \cap l$ as a list of (zero, one, or two) points sorted along *l*.
- list<real_point>* *C.intersection(const real_segment& s)*
returns $C \cap s$ as a list of (zero, one, or two) points sorted along *s*.
- real_segment* *C.left_tangent(const real_point& p)*
returns the line segment starting in *p* tangent to *C* and left of segment $[p, C.center()]$.
- real_segment* *C.right_tangent(const real_point& p)*
returns the line segment starting in *p* tangent to *C* and right of segment $[p, C.center()]$.
- real* *C.distance(const real_point& p)*
returns the distance between *C* and *p*.
- real* *C.sqr_dist(const real_point& p)*
returns the squared distance between *C* and *p*.

- real* *C*.distance(*const real_line& l*)
 returns the distance between *C* and *l*.
- real* *C*.distance(*const real_circle& D*)
 returns the distance between *C* and *D*.
- bool* radicalAxis(*const real_circle& C1, const real_circle& C2,*
 real_line& rad_axis)
 if the radical axis for *C1* and *C2* exists, it is assigned to *rad_axis* and true is returned; otherwise the result is false.

15.22 Real Triangles (`real_triangle`)

1. Definition

An instance t of the data type *real_triangle* is an oriented triangle in the two-dimensional plane. A triangle splits the plane into one bounded and one unbounded region. If the triangle is positively oriented, the bounded region is to the left of it, if it is negatively oriented, the unbounded region is to the left of it. A triangle t is called degenerate, if the 3 vertices of t are collinear.

```
#include < LEDA/geo/real_triangle.h >
```

2. Types

real_triangle::coord_type the coordinate type (*real*).

real_triangle::point_type the point type (*real_point*).

3. Creation

real_triangle t ; introduces a variable t of type *real_triangle*. t is initialized to the empty triangle.

real_triangle t (*const real_point*& p , *const real_point*& q , *const real_point*& r);
 introduces a variable t of type *real_triangle*. t is initialized to the triangle $[p, q, r]$.

real_triangle t (*real* $x1$, *real* $y1$, *real* $x2$, *real* $y2$, *real* $x3$, *real* $y3$);
 introduces a variable t of type *real_triangle*. t is initialized to the triangle $[(x1, y1), (x2, y2), (x3, y3)]$.

real_triangle t (*const triangle*& $t1$, *int* $prec = 0$);
 introduces a variable t of type *real_triangle* initialized to the triangle t_1 . (The second argument is for compatibility with *rat_triangle*.)

real_triangle t (*const rat_triangle*& $t1$);
 introduces a variable t of type *real_triangle* initialized to the triangle t_1 .

4. Operations

real_point t .point1() returns the first vertex of triangle t .

real_point t .point2() returns the second vertex of triangle t .

- real_point* *t*.point3() returns the third vertex of triangle *t*.
- real_point* *t*[*int* *i*] returns the *i*-th vertex of *t*. *Precondition*: $1 \leq i \leq 3$.
- int* *t*.orientation() returns the orientation of *t*.
- real* *t*.area() returns the signed area of *t* (positive, if *orientation*(*a*, *b*, *c*) > 0, negative otherwise).
- bool* *t*.is_degenerate() returns true if the vertices of *t* are collinear.
- int* *t*.side_of(*const real_point&* *p*)
returns +1 if *p* lies to the left of *t*, 0 if *p* lies on *t* and -1 if *p* lies to the right of *t*.
- region_kind* *t*.region_of(*const real_point&* *p*)
returns *BOUNDED_REGION* if *p* lies in the bounded region of *t*, *ON_REGION* if *p* lies on *t* and *UNBOUNDED_REGION* if *p* lies in the unbounded region.
- bool* *t*.inside(*const real_point&* *p*)
returns true, if *p* lies to the left of *t*.
- bool* *t*.outside(*const real_point&* *p*)
returns true, if *p* lies to the right of *t*.
- bool* *t*.on_boundary(*const real_point&* *p*)
decides whether *p* lies on the boundary of *t*.
- bool* *t*.contains(*const real_point&* *p*)
decides whether *t* contains *p*.
- bool* *t*.intersection(*const real_line&* *l*)
decides whether the bounded region or the boundary of *t* and *l* intersect.
- bool* *t*.intersection(*const real_segment&* *s*)
decides whether the bounded region or the boundary of *t* and *s* intersect.
- real_triangle* *t*.translate(*real dx*, *real dy*)
returns *t* translated by vector (*dx*, *dy*).
- real_triangle* *t*.translate(*const real_vector&* *v*)
returns *t* + *v*, i.e., *t* translated by vector *v*.
Precondition: *v*.dim() = 2.

real_triangle *t* + *const real_vector& v*

returns *t* translated by vector *v*.

real_triangle *t* - *const real_vector& v*

returns *t* translated by vector $-v$.

real_triangle *t*.rotate90(*const real_point& q*, *int i* = 1)

returns *t* rotated about *q* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

real_triangle *t*.rotate90(*int i* = 1)

returns *t*.rotate90(*t*.source(),*i*).

real_triangle *t*.reflect(*const real_point& p*, *const real_point& q*)

returns *t* reflected across the straight line passing through *p* and *q*.

real_triangle *t*.reflect(*const real_point& p*)

returns *t* reflected across point *p*.

real_triangle *t*.reverse()

returns *t* reversed.

15.23 Iso-oriented Real Rectangles (*real_rectangle*)

1. Definition

An instance r of the data type *real_rectangle* is an iso-oriented rectangle in the two-dimensional plane.

```
#include < LEDA/geo/real_rectangle.h >
```

2. Creation

```
real_rectangle  $r$ (const real_point&  $p$ , const real_point&  $q$ );
```

introduces a variable r of type *real_rectangle*. r is initialized to the *real_rectangle* with diagonal corners p and q

```
real_rectangle  $r$ (const real_point&  $p$ , real  $w$ , real  $h$ );
```

introduces a variable r of type *real_rectangle*. r is initialized to the *real_rectangle* with lower left corner p , width w and height h .

```
real_rectangle  $r$ (real  $x1$ , real  $y1$ , real  $x2$ , real  $y2$ );
```

introduces a variable r of type *real_rectangle*. r is initialized to the *real_rectangle* with diagonal corners $(x1, y1)$ and $(x2, y2)$.

```
real_rectangle  $r$ (const rectangle&  $r1$ , int  $prec = 0$ );
```

introduces a variable r of type *real_rectangle* initialized to the rectangle r_1 . (The second argument is for compatibility with *rat_rectangle*.)

```
real_rectangle  $r$ (const rat_rectangle&  $r1$ );
```

introduces a variable r of type *real_rectangle* initialized to the rectangle r_1 .

3. Operations

```
real_point  $r$ .upper_left() returns the upper left corner.
```

```
real_point  $r$ .upper_right() returns the upper right corner.
```

```
real_point  $r$ .lower_left() returns the lower left corner.
```

```
real_point  $r$ .lower_right() returns the lower right corner.
```

```
real_point  $r$ .center() returns the center of  $r$ .
```

```
list<real_point>  $r$ .vertices() returns the vertices of  $r$  in counter-clockwise order starting from the lower left point.
```

<i>real</i>	<i>r.xmin()</i>	returns the minimal x-coordinate of <i>r</i> .
<i>real</i>	<i>r.xmax()</i>	returns the maximal x-coordinate of <i>r</i> .
<i>real</i>	<i>r.ymin()</i>	returns the minimal y-coordinate of <i>r</i> .
<i>real</i>	<i>r.ymax()</i>	returns the maximal y-coordinate of <i>r</i> .
<i>real</i>	<i>r.width()</i>	returns the width of <i>r</i> .
<i>real</i>	<i>r.height()</i>	returns the height of <i>r</i> .
<i>bool</i>	<i>r.is_degenerate()</i>	returns true, if <i>r</i> degenerates to a segment or point (the 4 corners are collinear), false otherwise.
<i>bool</i>	<i>r.is_point()</i>	returns true, if <i>r</i> degenerates to a point.
<i>bool</i>	<i>r.is_segment()</i>	returns true, if <i>r</i> degenerates to a segment.
<i>int</i>	<i>r.cs_code(const real_point& p)</i>	returns the code for Cohen-Sutherland algorithm.
<i>bool</i>	<i>r.inside(const real_point& p)</i>	returns true, if <i>p</i> is inside of <i>r</i> , false otherwise.
<i>bool</i>	<i>r.outside(const real_point& p)</i>	returns true, if <i>p</i> is outside of <i>r</i> , false otherwise.
<i>bool</i>	<i>r.inside_or_contains(const real_point& p)</i>	returns true, if <i>p</i> is inside of <i>r</i> or on the border, false otherwise.
<i>bool</i>	<i>r.contains(const real_point& p)</i>	returns true, if <i>p</i> is on the border of <i>r</i> , false otherwise.
<i>region_kind</i>	<i>r.region_of(const real_point& p)</i>	returns BOUNDED_REGION if <i>p</i> lies in the bounded region of <i>r</i> , returns ON_REGION if <i>p</i> lies on <i>r</i> , and returns UNBOUNDED_REGION if <i>p</i> lies in the unbounded region.
<i>real_rectangle</i>	<i>r.include(const real_point& p)</i>	returns a new rectangle that includes the points of <i>r</i> and <i>p</i> .
<i>real_rectangle</i>	<i>r.include(const real_rectangle& r2)</i>	returns a new rectangle that includes the points of <i>r</i> and <i>r2</i> .

- real_rectangle* *r.translate(real dx, real dy)*
 returns a new rectangle that is the translation of *r* by (dx, dy) .
- real_rectangle* *r.translate(const real_vector& v)*
 returns a new rectangle that is the translation of *r* by *v*.
- real_rectangle* *r + const real_vector& v*
 returns *r* translated by *v*.
- real_rectangle* *r - const real_vector& v*
 returns *r* translated by $-v$.
- real_point* *r[int i]*
 returns the *i* - *th* vertex of *r*. Precondition: $(0 < i < 5)$.
- real_rectangle* *r.rotate90(const real_point& p, int i = 1)*
 returns *r* rotated about *p* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- real_rectangle* *r.rotate90(int i = 1)*
 returns *r* rotated by an angle of $i \times 90$ degrees about the origin.
- real_rectangle* *r.reflect(const real_point& p)*
 returns *r* reflected across *p*.
- list<real_point>* *r.intersection(const real_segment& s)*
 returns $r \cap s$.
- bool* *r.clip(const real_segment& t, real_segment& inter)*
 clips *t* on *r* and returns the result in *inter*.
- bool* *r.clip(const real_line& l, real_segment& inter)*
 clips *l* on *r* and returns the result in *inter*.
- bool* *r.clip(const real_ray& ry, real_segment& inter)*
 clips *ry* on *r* and returns the result in *inter*.
- bool* *r.difference(const real_rectangle& q, list<real_rectangle>& L)*
 returns *true* iff the difference of *r* and *q* is not empty, and *false* otherwise. The difference *L* is returned as a partition into rectangles.
- list<real_point>* *r.intersection(const real_line& l)*
 returns $r \cap l$.

list<*real_rectangle*> *r.intersection(const real_rectangle& s)*

returns $r \cap s$.

bool *r.do_intersect(const real_rectangle& b)*

returns *true* iff *r* and *b* intersect, false otherwise.

real *r.area()*

returns the area of *r*.

15.24 Geometry Algorithms (geo_alg)

All functions listed in this section work for geometric objects based on both floating-point and exact (rational) arithmetic. In particular, *point* can be replaced by *rat_point*, *segment* by *rat_segment*, and *circle* by *rat_circle*.

The floating point versions are faster but unreliable. They may produce incorrect results, abort, or run forever. Only the rational versions will produce correct results for all inputs.

The include-file for the rational version is `rat_geo_alg.h`, the include-file for the floating point version is `float_geo_alg.h`, and `geo_alg.h` includes both versions. Including both versions increases compile time. An alternative name for `geo_alg.h` is `plane_alg.h`.

• Convex Hulls

- list<point>* `CONVEX_HULL(const list<point>& L)`
 `CONVEX_HULL` takes as argument a list of points and returns the polygon representing the convex hull of L . The cyclic order of the vertices in the result list corresponds to counter-clockwise order of the vertices on the hull. The algorithm calls our current favorite of the algorithms below.
- polygon* `CONVEX_HULLPOLY(const list<point>& L)`
 as above, but returns the convex hull of L as a polygon.
- list<point>* `UPPER_CONVEX_HULL(const list<point>& L)`
 returns the upper convex hull of L .
- list<point>* `LOWER_CONVEX_HULL(const list<point>& L)`
 returns the lower convex hull of L .
- list<point>* `CONVEX_HULLS(const list<point>& L)`
 as above, but the algorithm is based on the sweep paradigm. Running time is $O(n \log n)$ in the worst and in the best case.
- list<point>* `CONVEX_HULLIC(const list<point>& L)`
 as above, but the algorithm is based on incremental construction. The running time is $O(n^2)$ worst case and is $O(n \log n)$ expected case. The expectation is computed as the average over all permutations of L . The running time is linear in the best case.
- list<point>* `CONVEX_HULLRIC(const list<point>& L)`
 as above. The algorithm permutes L randomly and then calls the preceding function.

double WIDTH(*const list<point>& L, line& l1, line& l2*)
 returns the square of the minimum width of a stripe covering all points in L and the two boundaries of the stripe.
Precondition: L is non-empty

• Halfplane intersections

void HALFPLANE_INTERSECTION(*const list<line>& L, list<line>& Lout*)
 For every line $\ell \in L$ let h_ℓ be the closed halfplane lying on the positive side of ℓ , i.e., $h_\ell = \{ p \in \mathbb{R}^2 \mid \text{orientation}(\ell, p) \geq 0 \}$, and let $H = \bigcap_{\ell \in L} h_\ell$. Then HALFPLANE_INTERSECTION computes the list of lines $Lout$ defining the boundary of H in counter-clockwise ordering.

• Point Location

edge LOCATE_IN_TRIANGULATION(*const GRAPH<point, int>& G, point p, edge start = 0*)
 returns an edge e of triangulation G that contains p or that borders the face that contains p . In the former case, a hull edge is returned if p lies on the boundary of the convex hull. In the latter case we have $\text{orientation}(e, p) > 0$ except if all points of G are collinear and p lies on the induced line. In this case $\text{target}(e)$ is visible from p . The function returns *nil* if G has no edge. The optional third argument is an edge of G , where the *locate* operation starts searching.

edge LOCATE_IN_TRIANGULATION(*const GRAPH<point, segment>& G, point p, edge start = 0*)
 as above, for constraint triangulations.

edge LOCATE_IN_TRIANGULATION(*const graph& G, const node_array<point>& pos, point p, edge start = 0*)
 as above, for arbitrary graph types representing a triangulation. Node positions have to be supplied in a *node_array pos*.

• Triangulations

edge TRIANGULATE_POINTS(*const list<point>& L, GRAPH<point, int>& T*)
 computes a triangulation (planar map) T of the points in L and returns an edge of the outer face (convex hull).

void DELAUNAY_TRIANG(*const list<point>& L, GRAPH<point, int>& DT*)
 computes the delaunay triangulation DT of the points in L .

void DELAUNAY_DIAGRAM(*const list<point>& L, GRAPH<point, int>& DD*)
 computes the delaunay diagram DD of the points in L .

void F_DELAUNAY_TRIANG(*const list<point>& L*, *GRAPH<point, int>& FDT*)
 computes the furthest point delaunay triangulation *FDT* of the points in *L*.

void F_DELAUNAY_DIAGRAM(*const list<point>& L*, *GRAPH<point, int>& FDD*)
 computes the furthest point delaunay diagram *FDD* of the points in *L*.

• Constraint Triangulations

edge TRIANGULATE_SEGMENTS(*const list<segment>& L*,
GRAPH<point, segment>& G)
 computes a constrained triangulation (planar map) *T* of the segments in *L* (trivial segments representing points are allowed). The function returns an edge of the outer face (convex hull).

edge DELAUNAY_TRIANG(*const list<segment>& L*, *GRAPH<point, segment>& G*)
 computes a constrained Delaunay triangulation *T* of the segments in *L*. The function returns an edge of the outer face (convex hull).

edge TRIANGULATE_PLANE_MAP(*GRAPH<point, segment>& G*)
 computes a constrained triangulation *T* of the plane map (counterclockwise straight-line embedded Graph) *G*. The function returns an edge of the outer face (convex hull). *Precondition*: *G* is simple.

edge DELAUNAY_TRIANG(*GRAPH<point, segment>& G*)
 computes a constrained Delaunay triangulation *T* of the plane map *G*. The function returns an edge of the outer face (convex hull). *Precondition*: *G* is simple.

edge TRIANGULATE_POLYGON(*const polygon& P*, *GRAPH<point, segment>& G*,
list<edge>& inner_edges, *list<edge>& outer_edges*,
list<edge>& boundary_edges)
 triangulates the interior and exterior of the simple polygon *P* and stores all edges of the inner (outer) triangulation in *inner_edges* (*outer_edges*) and the edges of the polygon boundary in *boundary_edges*. The function returns an edge of the convex hull of *P* if *P* is simple and *nil* otherwise.

edge TRIANGULATE_POLYGON(*const gen_polygon*& *GP*,
GRAPH<*point*, *segment*>& *G*,
list<*edge*>& *inner_edges*, *list*<*edge*>& *outer_edges*,
list<*edge*>& *boundary_edges*, *list*<*edge*>& *hole_edges*)
triangulates the interior and exterior of the generalized polygon *GP* and stores all edges of the inner (outer) triangulation in *inner_edges* (*outer_edges*). The function returns *nil* if *GP* is trivial, and an edge of the convex hull otherwise. *boundary_edges* contains the edges of every counter-clockwise oriented boundary cycle of *GP*, and *hole_edges* contains the edges on every clockwise oriented boundary cycle of *GP*. Note that the reversals of boundary and hole edges will be returned in *inner_edges*.
Precondition: *GP* is simple.

edge CONVEX_COMPONENTS(*const polygon*& *P*, *GRAPH*<*point*, *segment*>& *G*,
list<*edge*>& *inner_edges*, *list*<*edge*>& *boundary*)
if *P* is a bounded and non-trivial simple polygon its interior is decomposed into convex parts. All inner edges of the constructed decomposition are returned in *inner_edges*. *boundary_edges* contains the edges of the polygon boundary. Note that the reversals of boundary edges will be stored in *inner_edges*. The function returns an edge of the convex hull if *P* is simple and non-trivial and *nil* otherwise.

edge CONVEX_COMPONENTS(*const gen_polygon*& *GP*,
GRAPH<*point*, *segment*>& *G*,
list<*edge*>& *inner_edges*, *list*<*edge*>& *boundary_edges*,
list<*edge*>& *hole_edges*)
if *GP* is a bounded and non-trivial generalized polygon, its interior is decomposed into convex parts. All inner edges of the constructed decomposition are returned in *inner_edges*. *boundary_edges* contains the edges of every counter-clockwise oriented boundary cycle of *GP*, and *hole_edges* contains the edges of every clockwise oriented boundary cycle of *GP*. Note that the reversals of boundary and hole edges will be stored in *inner_edges*. The function returns an edge of the convex hull if *GP* is a bounded and non-trivial and *nil* otherwise. *Precondition*: *GP* must be simple.

list<*polygon*> TRIANGLE_COMPONENTS(*const gen_polygon*& *GP*)
triangulates the interior of generalized polygon *GP* and returns the result of the triangulation as a list of polygons.

list<*polygon*> CONVEX_COMPONENTS(*const gen_polygon*& *GP*)
if *GP* is a bounded and non-trivial generalized polygon, its interior is decomposed into convex parts. The function returns a list of polygons that form the convex decomposition of *GP*'s interior.

• Minkowski Sums

Please note that the Minkowski sums only work reliably for the rational kernel.

gen_polygon MINKOWSKLSUM(*const polygon& P, const polygon& R*)

computes the Minkowski sum of *P* and *R*.

gen_polygon MINKOWSKLDIFF(*const polygon& P, const polygon& R*)

computes the Minkowski difference of *P* and *R*, i.e. the Minkowski sum of *P* and *R.reflect(point(0,0))*.

gen_polygon MINKOWSKLSUM(*const gen_polygon& P, const polygon& R*)

computes the Minkowski sum of *P* and *R*.

gen_polygon MINKOWSKLDIFF(*const gen_polygon& P, const polygon& R*)

computes the Minkowski difference of *P* and *R*, i.e. the Minkowski sum of *P* and *R.reflect(point(0,0))*.

The following variants of the *MINKOWSKI* functions take two additional call-back function arguments *conv_partition* and *conv_unite* which are used by the algorithm to partition the input polygons into convex parts and for computing the union of a list of convex polygons, respectively (instead of using the default methods).

gen_polygon MINKOWSKLSUM(*const polygon& P, const polygon& R,*
*void (*conv_partition)(const gen_polygon& p,*
const polygon& r, list<polygon>& lp,
list<polygon>& lr),
*gen_polygon (*conv_unite)(const list<gen_polygon>&)*)

gen_polygon MINKOWSKLDIFF(*const polygon& P, const polygon& R,*
*void (*conv_partition)(const gen_polygon& p,*
const polygon& r, list<polygon>& lp,
list<polygon>& lr),
*gen_polygon (*conv_unite)(const list<gen_polygon>&)*)

gen_polygon MINKOWSKLSUM(*const gen_polygon& P, const polygon& R,*
*void (*conv_partition)(const gen_polygon& p,*
const polygon& r, list<polygon>& lp,
list<polygon>& lr),
*gen_polygon (*conv_unite)(const list<gen_polygon>&)*)

gen_polygon MINKOWSKLDIFF(*const gen_polygon& P, const polygon& R,*
*void (*conv_partition)(const gen_polygon& p,*
const polygon& r, list<polygon>& lp,
list<polygon>& lr),
*gen_polygon (*conv_unite)(const list<gen_polygon>&)*)

• Euclidean Spanning Trees

void MIN_SPANNING_TREE(*const list<point>& L, GRAPH<point, int>& T*)

computes the Euclidian minimum spanning tree *T* of the points in *L*.

• Triangulation Checker

bool IsConvexSubdivision(*const GRAPH<point, int>& G*)
 returns true if G is a convex planar subdivision.

bool IsTriangulation(*const GRAPH<point, int>& G*)
 returns true if G is convex planar subdivision in which every bounded face is a triangle or if all nodes of G lie on a common line.

bool IsDelaunayTriangulation(*const GRAPH<point, int>& G*,
delaunay_voronoi_kind kind)
 checks whether G is a nearest (*kind* = *NEAREST*) or furthest (*kind* = *FURTHEST*) site Delaunay triangulation of its vertex set. G is a Delaunay triangulation iff it is a triangulation and all triangles have the Delaunay property. A triangle has the Delaunay property if no vertex of an adjacent triangle is contained in the interior (*kind* = *NEAREST*) or exterior (*kind* = *FURTHEST*) of the triangle.

bool IsDelaunayDiagram(*const GRAPH<point, int>& G*, *delaunay_voronoi_kind kind*)
 checks whether G is a nearest (*kind* = *NEAREST*) or furthest (*kind* = *FURTHEST*) site Delaunay diagram of its vertex set. G is a Delaunay diagram if it is a convex subdivision, if the vertices of any bounded face are co-circular, and if every triangulation of G is a Delaunay triangulation.

• Voronoi Diagrams

void VORONOI(*const list<point>& L*, *GRAPH<circle, point>& VD*)
 VORONOI takes as input a list of points (sites) L . It computes a directed graph VD representing the planar subdivision defined by the Voronoi diagram of L . For each node v of VD $G[v]$ is the corresponding Voronoi vertex (*point*) and for each edge e $G[e]$ is the site (*point*) whose Voronoi region is bounded by e . The algorithm has running time $O(n^2)$ in the worst case and $O(n \log n)$ with high probability, where n is the number of sites.

void F_VORONOI(*const list<point>& L*, *GRAPH<circle, point>& FVD*)
 computes the farthest point Voronoi Diagram FVD of the points in L .

circle LARGEST_EMPTY_CIRCLE(*const list<point>& L*)
 computes a largest circle whose center lies inside the convex hull of L that contains no point of L in its interior. Returns the trivial circle if L is empty.

circle SMALLEST_ENCLOSING_CIRCLE(*const list<point>& L*)
 computes a smallest circle containing all points of L in its interior.

void ALLEEMPTY_CIRCLES(*const list<point>& L, list<circle>& CL*)

computes the list *CL* of all empty circles passing through three or more points of *L*.

void ALLENCLOSING_CIRCLES(*const list<point>& L, list<circle>& CL*)

computes the list *CL* of all enclosing circles passing through three or more points of *L*.

An annulus is either the region between two concentric circles or the region between two parallel lines.

bool MIN_AREA_ANNULUS(*const list<point>& L, point& center, point& ipoint, point& opoint, line& l1*)

computes the minimum area annulus containing the points of *L*. The function returns false if all points in *L* are collinear and returns true otherwise. In the former case a line passing through the points in *L* is returned in *l1*, and in the latter case the annulus is returned by its *center* and a point on the inner and the outer circle, respectively.

bool MIN_WIDTH_ANNULUS(*const list<point>& L, point& center, point& ipoint, point& opoint, line& l1, line& l2*)

computes the minimum width annulus containing the points of *L*. The function returns false if the minimum width annulus is a stripe and returns true otherwise. In the former case the boundaries of the stripes are returned in *l1* and *l2* and in the latter case the annulus is returned by its *center* and a point on the inner and the outer circle, respectively.

void CRUST(*const list<point>& L0, GRAPH<point, int>& G*)

takes a list *L0* of points and traces to guess the curve(s) from which *L0* are sampled. The algorithm is due to Amenta, Bern, and Eppstein. The algorithm is guaranteed to succeed if *L0* is a sufficiently dense sample from a smooth closed curve.

bool IsVoronoiDiagram(*const* GRAPH<*circle, point*>& *G*, *delaunay_voronoi_kind* *kind*)

checks whether *G* represents a nearest (*kind* = *NEAREST*) or furthest (*kind* = *FURTHEST*) site Voronoi diagram.

Voronoi diagrams of point sites are represented as planar maps as follows: There is a vertex for each vertex of the Voronoi diagram and, in addition, a vertex “at infinity” for each ray of the Voronoi diagram. Vertices at infinity have degree one. The edges of the graph correspond to the edges of the Voronoi diagram. The chapter on Voronoi diagrams of the LEDA-book [64] contains more details. Each edge is labeled with the site (class *POINT*) owning the region to its left and each vertex is labeled with a triple of points (= the three defining points of a *CIRCLE*). For a “finite” vertex the three points are any three sites associated with regions incident to the vertex (and hence the center of the circle is the position of the vertex in the plane) and for a vertex at infinity the three points are collinear and the first point and the third point of the triple are the sites whose regions are incident to the vertex at infinity. Let *a* and *c* be the first and third point of the triple respectively; *a* and *c* encode the geometric position of the vertex at infinity as follows: the vertex lies on the perpendicular bisector of *a* and *c* and to the left of the segment *ac*.

• Line Segment Intersection

void SEGMENT_INTERSECTION(*const* list<*segment*>& *S*,
GRAPH<*point, segment*>& *G*, *bool* *embed* = *false*)

takes a list of segments *S* as input and computes the planar graph *G* induced by the set of straight line segments in *S*. The nodes of *G* are all endpoints and all proper intersection points of segments in *S*. The edges of *G* are the maximal relatively open subsegments of segments in *S* that contain no node of *G*. The edges are directed as the corresponding segments. If the flag *embed* is true, the corresponding planar map is computed. Note that for each edge *e* *G*[*e*] is the input segment that contains *e* (see the LEDA book for details).

void SWEEP_SEGMENTS(*const* list<*segment*>& *S*, GRAPH<*point, segment*>& *G*,
bool *embed* = *false*, *bool* *use_optimization* = *true*)

as above.

The algorithm ([11]) runs in time $O((n + s) \log n + m)$, where *n* is the number of segments, *s* is the number of vertices of the graph *G*, and *m* is the number of edges of *G*. If *S* contains no overlapping segments then $m = O(n + s)$. If *embed* is true the running time increases by $O(m \log m)$. If *use_optimization* is true an optimization described in the LEDA book is used.

void MULMULEY_SEGMENTS(*const list<segment>& S*,
 GRAPH<point, segment>& G, *bool embed = false*)

as above.

There is one additional output convention. If G is an undirected graph, the undirected planar map corresponding to $G(s)$ is computed. The computation follows the incremental algorithm of Mulmuley ([68]) whose expected running time is $O(M + s + n \log n)$, where n is the number of segments, s is the number of vertices of the graph G , and m is the number of edges.

void SEGMENT_INTERSECTION(*const list<segment>& S*,
 *void (*report)(const segment& , const segment&)*)

takes a list of segments S as input and executes for every pair (s_1, s_2) of intersecting segments $report(s_1, s_2)$. The algorithm ([6]) has running time $O(n \log^2 n + k)$, where n is the number of segments and k is the number intersecting pairs of segments.

void SEGMENT_INTERSECTION(*const list<segment>& S*, *list<point>& P*)

takes a list of segments S as input, computes the set of (proper) intersection points between all segments in S and stores this set in P . The algorithm ([11]) has running time $O((|P| + |S|) \log |S|)$.

• Red-Blue Line Segment Intersection

void SEGMENT_INTERSECTION(*const list<segment>& S1*, *const list<segment>& S2*,
 GRAPH<point, segment>& G, *bool embed = false*)

takes two lists of segments S_1 and S_2 as input and computes the planar graph G induced by the set of straight line segments in $S_1 \cup S_2$ (as defined above). *Precondition:* Any pair of segments in S_1 or S_2 , respectively, does not intersect in a point different from one of the endpoints of the segments, i.e. segments of S_1 or S_2 are either pairwise disjoint or have a common endpoint.

• Closest Pairs

double CLOSEST_PAIR(*list<point>& L*, *point& r1*, *point& r2*)

CLOSEST_PAIR takes as input a list of points L . It computes a pair of points $r1, r2 \in L$ with minimal Euclidean distance and returns the squared distance between $r1$ and $r2$. The algorithm ([76]) has running time $O(n \log n)$ where n is the number of input points.

• Miscellaneous Functions

void BoundingBox(*const list<point>& L*, *point& pl*, *point& pb*, *point& pr*, *point& pt*)
 computes four points pl, pb, pr, pt from L such that $(xleft, ybot, xright, ytop)$ with $xleft = pl.xcoord()$, $ybot = pb.ycoord()$, $xright = pr.xcoord()$ and $ytop = pt.ycoord()$ is the smallest iso-oriented rectangle containing all points of L . *Precondition:* L is not empty.

bool IsSimplePolygon(*const list<point>& L*)
 takes as input a list of points L and returns *true* if L is the vertex sequence of a simple polygon and false otherwise. The algorithm has running time $O(n \log n)$, where n is the number of points in L .

node NestingTree(*const gen_polygon& P*, *GRAPH<polygon, int>& T*)
 The nesting tree T of a generalized polygon P is defined as follows. Every node v in T is labelled with a polygon $T[v]$ from the boundary representation of P , except for root r of T which is labelled with the empty polygon. The root symbolizes the whole two-dimensional plane. There is an edge (u, v) (with $u \neq r$) in T iff the bounded region of $T[v]$ is directly nested in $T[u]$. The term "directly" means that there is no node w different from u and v such that $T[v]$ is nested in $T[w]$ and $T[w]$ is nested in $T[u]$. And there is an edge (r, v) iff $T[v]$ is not nested in any other polygon of P . The function computes the nesting tree of P and returns its root. (The running time of the function depends on the order of the polygons in the boundary representation of P . The closer directly nested polygons are, the better.)

• Properties of Geometric Graphs

We give procedures to check properties of geometric graph. We give procedures to verify properties of *geometric graph*. A geometric graph is a straight-line embedded map. Every node is mapped to a point in the plane and every dart is mapped to the line segment connecting its endpoints.

We use *geo_graph* as a template parameter for geometric graph. Any instantiation of *geo_graph* must provide a function

VECTOR edge_vector(*const geo_graph& G*, *const edge& e*)

that returns a vector from the source to the target of e . In order to use any of these template functions the file `/LEDA/geo/generic/geo_check.h` must be included.

template <class *geo_graph*>

bool IsCCW_Ordered(*const geo_graph& G*)

returns true if for all nodes v the neighbors of v are in increasing counter-clockwise order around v .

```
template <class geo_graph>
```

```
bool Is_CCW_Weakly_Ordered(const geo_graph& G)
```

returns true if for all nodes v the neighbors of v are in non-decreasing counter-clockwise order around v .

```
template <class geo_graph>
```

```
bool Is_CCW_OrderedPlane_Map(const geo_graph& G)
```

Equivalent to *Is_Plane_Map*(G) and *Is_CCW_Ordered*(G).

```
template <class geo_graph>
```

```
bool Is_CCW_Weakly_OrderedPlane_Map(const geo_graph& G)
```

Equivalent to *Is_Plane_Map*(G) and *Is_CCW_Weakly_Ordered*(G).

```
template <class geo_graph>
```

```
void SORT_EDGES(geo_graph& G)
```

Reorders the edges of G such that for every node v the edges in $A(v)$ are in non-decreasing order by angle.

```
template <class geo_graph>
```

```
bool Is_CCW_Convex_Face_Cycle(const geo_graph& G, const edge& e)
```

returns true if the face cycle of G containing e defines a counter-clockwise convex polygon, i.e, if the face cycle forms a cyclically increasing sequence of edges according to the compare-by-angles ordering.

```
template <class geo_graph>
```

```
bool Is_CCW_Weakly_Convex_Face_Cycle(const geo_graph& G, const edge& e)
```

returns true if the face cycle of G containing e defines a counter-clockwise weakly convex polygon, i.e, if the face cycle forms a cyclically non-decreasing sequence of edges according to the compare-by-angles ordering.

```
template <class geo_graph>
```

```
bool Is_CW_Convex_Face_Cycle(const geo_graph& G, const edge& e)
```

returns true if the face cycle of G containing e defines a clockwise convex polygon, i.e, if the face cycle forms a cyclically decreasing sequence of edges according to the compare-by-angles ordering.

```
template <class geo_graph>
```

```
bool Is_CW_Weakly_Convex_Face_Cycle(const geo_graph& G, const edge& e)
```

returns true if the face cycle of G containing e defines a clockwise weakly convex polygon, i.e, if the face cycle forms a cyclically non-increasing sequence of edges according to the compare-by-angles ordering.

15.25 Transformation (TRANSFORM)

1. Definition

There are three instantiations of *TRANSFORM*: *transform* (floating point kernel), *rat_transform* (rational kernel) and *real_transform* (real kernel). The respective header file name corresponds to the type name (with “.h” appended).

An instance T of type *TRANSFORM* is an affine transformation of two-dimensional space. It is given by a 3×3 matrix T with $T_{2,0} = T_{2,1} = 0$ and $T_{2,2} \neq 0$ and maps the point p with homogeneous coordinate vector (p_x, p_y, p_w) to the point $T \cdot p$.

A matrix of the form

$$\begin{pmatrix} w & 0 & x \\ 0 & w & y \\ 0 & 0 & w \end{pmatrix}$$

realizes an translation by the vector $(x/w, y/w)$ and a matrix of the form

$$\begin{pmatrix} a & -b & 0 \\ b & a & 0 \\ 0 & 0 & w \end{pmatrix}$$

where $a^2 + b^2 = w^2$ realizes a rotation by the angle α about the origin, where $\cos \alpha = a/w$ and $\sin \alpha = b/w$. Rotations are in counter-clockwise direction.

```
#include < LEDA/geo/generic/TRANSFORM.h >
```

2. Creation

TRANSFORM T ; creates a variable introduces a variable T of type *TRANSFORM*.
 T is initialized with the identity transformation.

TRANSFORM T (*const* *INT_MATRIX* t);

introduces a variable T of type *TRANSFORM*. T is initialized with the matrix t .

Precondition: t is a 3×3 matrix with $t_{2,0} = t_{2,1} = 0$ and $t_{2,2} \neq 0$.

3. Operations

INT_MATRIX T .*T_matrix*() returns the transformation matrix

void T .*simplify*() The operation has no effect for *transform*. For *rat_transform* let g be the ggT of all matrix entries. Cancels out g .

RAT_TYPE T .*norm*() returns the norm of the transformation

TRANSFORM $T(\text{const } \text{TRANSFORM}\& T1)$
 returns the transformation $T \circ T1$.

POINT $T(\text{const } \text{POINT}\& p)$ returns $T(p)$.

VECTOR $T(\text{const } \text{VECTOR}\& v)$
 returns $T(v)$.

SEGMENT $T(\text{const } \text{SEGMENT}\& s)$
 returns $T(s)$.

LINE $T(\text{const } \text{LINE}\& l)$ returns $T(l)$.

RAY $T(\text{const } \text{RAY}\& r)$ returns $T(r)$.

CIRCLE $T(\text{const } \text{CIRCLE}\& C)$
 returns $T(C)$.

POLYGON $T(\text{const } \text{POLYGON}\& P)$
 returns $T(P)$.

GEN_POLYGON $T(\text{const } \text{GEN_POLYGON}\& P)$
 returns $T(P)$.

Non-member Functions

In any of the function below a point can be specified to the origin by replacing it by an anonymous object of type `POINT`, e.g., `rotation90(POINT())` will generate a rotation about the origin.

TRANSFORM `translation(const INT_TYPE& dx, const INT_TYPE& dy,
 const INT_TYPE& dw)`
 returns the translation by the vector $(dx/dw, dy/dw)$.

TRANSFORM `translation(const RAT_TYPE& dx, const RAT_TYPE& dy)`
 returns the translation by the vector (dx, dy) .

TRANSFORM `translation(const VECTOR& v)`
 returns the translation by the vector v .

TRANSFORM `rotation(const POINT& q, double alpha, double eps)`
 returns the rotation about q by an angle $alpha \pm eps$.

TRANSFORM `rotation90(const POINT& q)`
 returns the rotation about q by an angle of 90 degrees.

TRANSFORM reflection(*const POINT*& *q*, *const POINT*& *r*)

returns the reflection across the straight line passing through *q* and *r*.

TRANSFORM reflection(*const POINT*& *q*)

returns the reflection across point *q*.

15.26 Point Generators (point generators)

All generators are available for *point*, *rat_point*, *real_point*, *d3_point*, and *d3_rat_point*. We use *POINT* to stand for any of these classes. The corresponding header files are called `random_point.h`, `random_rat_point.h`, `random_real_point.h`, `random_d3_point.h`, and `random_d3_rat_point.h`, respectively. These header files are included in the corresponding kernel header files, e.g., `random_rat_point.h` is part of `rat_kernel.h`.

We use the following naming conventions: *square*, *circle*, *segment*, and *disk* refer to two-dimensional objects (even in 3d) and *cube*, *ball*, and *sphere* refer to full-dimensional objects, i.e, in 2d *cube* and *square*, *ball* and *disk*, and *circle* and *sphere* are synonymous.

void `random_point_in_square(POINT& p, int maxc)`
 returns a point whose *x* and *y*-coordinates are random integers in $[-maxc .. maxc]$. The *z*-coordinate is zero.

void `random_points_in_square(int n, int maxc, list<POINT>& L)`
 returns a list *L* of *n* points

void `random_point_in_unit_square(POINT& p, int D = (1 << 30) - 1)`
 returns a point whose coordinates are random rationals of the form i/D where *i* is a random integer in the range $[0 .. D]$. The default value of *D* is $2^{30} - 1$.

void `random_points_in_unit_square(int n, int D, list<POINT>& L)`
 returns a list *L* of *n* points

void `random_points_in_unit_square(int n, list<POINT>& L)`
 returns a list *L* of *n* points The default value of *D* is used.

void `random_point_in_cube(POINT& p, int maxc)`
 returns a point whose coordinates are random integers in $[-maxc .. maxc]$. In 2d this function is equivalent to `random_point_in_square`.

void `random_points_in_cube(int n, int maxc, list<POINT>& L)`
 returns a list *L* of *n* points

void `random_point_in_unit_cube(POINT& p, int D = (1 << 30) - 1)`
 returns a point whose coordinates are random rationals of the form i/D where *i* is a random integer in the range $[0 .. D]$. The default value of *D* is $2^{30} - 1$.

void `random_points_in_unit_cube(int n, int D, list<POINT>& L)`
 returns a list *L* of *n* points

- void* random_points_in_unit_cube(*int* n , *list*<POINT>& L)
as above, but the default value of D is used.
- void* random_point_in_disc(POINT& p , *int* R)
returns a random point with integer x and y -coordinates in the disc with radius R centered at the origin. The z -coordinate is zero.
Precondition: $R \leq 2^{30}$.
- void* random_points_in_disc(*int* n , *int* R , *list*<POINT>& L)
returns a list L of n points
- void* random_point_in_unit_disc(POINT& p , *int* $D = (1 \ll 30) - 1$)
returns a point in the unit disc whose coordinates are quotients with denominator D . The default value of D is $2^{30} - 1$.
- void* random_points_in_unit_disc(*int* n , *int* D , *list*<POINT>& L)
returns a list L of n points
- void* random_points_in_unit_disc(*int* n , *list*<POINT>& L)
returns a list L of n points The default value of D is used.
- void* random_point_in_ball(POINT& p , *int* R)
returns a random point with integer coordinates in the ball with radius R centered at the origin. In 2d this function is equivalent to *random_point_in_disc*.
Precondition: $R \leq 2^{30}$.
- void* random_points_in_ball(*int* n , *int* R , *list*<POINT>& L)
returns a list L of n points
- void* random_point_in_unit_ball(POINT& p , *int* $D = (1 \ll 30) - 1$)
returns a point in the unit ball whose coordinates are quotients with denominator D . The default value of D is $2^{30} - 1$.
- void* random_points_in_unit_ball(*int* n , *int* D , *list*<POINT>& L)
returns a list L of n points
- void* random_points_in_unit_ball(*int* n , *list*<POINT>& L)
returns a list L of n points The default value of D is used.
- void* random_point_near_circle(POINT& p , *int* R)
returns a random point with integer coordinates that lies close to the circle with radius R centered at the origin.

- void* `random_points_near_circle(int n, int R, list<POINT>& L)`
returns a list L of n points
- void* `random_point_near_unit_circle(POINT& p, int D = (1 ≪ 30) - 1)`
returns a point close to the unit circle whose coordinates are quotients with denominator D . The default value of D is $2^{30} - 1$.
- void* `random_points_near_unit_circle(int n, int D, list<POINT>& L)`
returns a list L of n points
- void* `random_points_near_unit_circle(int n, list<POINT>& L)`
returns a list L of n points The default value of D is used.
- void* `random_point_near_sphere(POINT& p, int R)`
returns a point with integer coordinates close to the sphere with radius R centered at the origin.
- void* `random_points_near_sphere(int n, int R, list<POINT>& L)`
returns a list L of n points
- void* `random_point_near_unit_sphere(POINT& p, int D = (1 ≪ 30) - 1)`
returns a point close to the unit sphere whose coordinates are quotients with denominator D . In 2d this function is equivalent to `point_near_unit_circle`.
- void* `random_points_near_unit_sphere(int n, int D, list<POINT>& L)`
returns a list L of n points
- void* `random_points_near_unit_sphere(int n, list<POINT>& L)`
returns a list L of n points The default value of D is used.

With the rational kernel the functions `_on_circle` are guaranteed to produce points that lie precisely on the specified circle. With the floating point kernel the functions are equivalent to the `_near_circle` functions.

- void* `random_point_on_circle(POINT& p, int R, int C = 1000000)`
returns a random point with integer coordinates that lies on the circle with radius R centered at the origin. The point is chosen from a set of at least C candidates.
- void* `random_points_on_circle(int n, int R, list<POINT>& L, int C = 1000000)`
returns a list L of n points
- void* `random_point_on_unit_circle(POINT& p, int C = 1000000)`
returns a point on the unit circle. The point is chosen from a set of at least C candidates.

- void* `random_points_on_unit_circle(int n, list<POINT>& L, int C = 1000000)`
returns a list L of n points
- void* `random_point_on_sphere(POINT& p, int R)`
same as `random_point_near_sphere`.
- void* `random_points_on_sphere(int n, int R, list<POINT>& L)`
returns a list L of n points
- void* `random_point_on_unit_sphere(POINT& p, int D = (1 << 30) - 1)`
same as `random_point_near_unit_sphere`.
- void* `random_points_on_unit_sphere(int n, int D, list<POINT>& L)`
returns a list L of n points
- void* `random_points_on_unit_sphere(int n, list<POINT>& L)`
returns a list L of n points The default value of D is used.
- void* `random_point_on_segment(POINT& p, SEGMENT s)`
generates a random point on s .
- void* `random_points_on_segment(SEGMENT s, int n, list<POINT>& L)`
generates a list L of n points
- void* `points_on_segment(SEGMENT s, int n, list<POINT>& L)`
generates a list L of n equally spaced points on s .
- void* `random_point_on_paraboloid(POINT& p, int maxc)`
returns a point (x, y, z) with x and y random integers in the range $[-maxc .. maxc]$, and $z = 0.004 * (x * x + y * y) - 1.25 * maxc$. The function does not make sense in 2d.
- void* `random_points_on_paraboloid(int n, int maxc, list<POINT>& L)`
returns a list L of n points
- void* `lattice_points(int n, int maxc, list<POINT>& L)`
returns a list L of approximately n points. The points have integer coordinates $id/maxc$ for an appropriately chosen d and $-maxc/d \leq i \leq maxc/d$.
- void* `random_points_on_diagonal(int n, int maxc, list<POINT>& L)`
generates n points on the diagonal whose coordinates are random integer in the range from $-maxc$ to $maxc$.

15.27 Point on Rational Circle (*r_circle_point*)

1. Definition

An instance p of type *r_circle_point* is a point in the two-dimensional plane that can be obtained by intersecting a rational circle c and a rational line l (cf. Sections 15.14 and 15.13). Note that c and l may intersect in two points p_1 and p_2 . Assume that we order these intersections along the (directed) line l . Then p is uniquely determined by a triple $(c, l, which)$, where *which* is either *first* or *second*. Observe that the coordinates of p are in general non-rational numbers (because their computation involves square roots). Therefore the class *r_circle_point* is derived from *real_point* (see Section 15.17), which means that all operations of *real_point* are available.

```
#include < LEDA/geo/r_circle_point.h >
```

2. Types

```
r_circle_point::tag { first, second }
```

used for selecting between the two possible intersections of a circle and a line.

3. Creation

```
r_circle_point p;            creates an instance  $p$  initialized to the point (0,0).
```

```
r_circle_point p(const rat_point& rat_pnt);  
                              creates an instance  $p$  initialized to the rational point rat_pnt.
```

```
r_circle_point p(const point& pnt);  
                              creates an instance  $p$  initialized to the point pnt.
```

```
r_circle_point p(const rat_circle& c, const rat_line& l, tag which);  
                              creates an instance  $p$  initialized to the point determined by  
( $c, l, which$ ) (see above).
```

```
r_circle_point p(const real_point& rp, const rat_circle& c, const rat_line& l, tag which);  
                              creates an instance  $p$  initialized to the real point rp.  
                              Precondition: rp is the point described by ( $c, l, which$ ).
```

4. Operations

```
void            p.normalize()            simplifies the internal representation of  $p$ .
```

```
rat_circle     p.supporting_circle()    returns a rational circle passing through  $p$ .
```

```
rat_line       p.supporting_line()      returns a rational line passing through  $p$ .
```

<i>tag</i>	<i>p</i> .which_intersection()	returns whether <i>p</i> is the first or the second intersection of the supporting circle and the supporting line.
<i>bool</i>	<i>p</i> .is_rat_point()	returns true, if <i>p</i> can be converted to <i>rat_point</i> . (The value false means “do not know”.)
<i>const rat_point&</i>	<i>p</i> .to_rat_point()	converts <i>p</i> to a <i>rat_point</i> . Precondition: <i>is_rat_point</i> returns true.
<i>rat_point</i>	<i>p</i> .approximate_by_rat_point()	approximates <i>p</i> by a <i>rat_point</i> .
<i>r_circle_point</i>	<i>p</i> .round(<i>int prec</i> = 0)	returns a rounded representation of <i>p</i> . (experimental)
<i>r_circle_point</i>	<i>p</i> .translate(<i>rational dx</i> , <i>rational dy</i>)	returns <i>p</i> translated by vector (<i>dx</i> , <i>dy</i>).
<i>r_circle_point</i>	<i>p</i> .translate(<i>const rat_vector& v</i>)	returns <i>p</i> translated by vector <i>v</i> .
<i>r_circle_point</i>	<i>p</i> + <i>const rat_vector& v</i>	returns <i>p</i> translated by vector <i>v</i> .
<i>r_circle_point</i>	<i>p</i> - <i>const rat_vector& v</i>	returns <i>p</i> translated by vector $-v$.
<i>r_circle_point</i>	<i>p</i> .rotate90(<i>const rat_point& q</i> , <i>int i</i> = 1)	returns <i>p</i> rotated about <i>q</i> by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
<i>r_circle_point</i>	<i>p</i> .reflect(<i>const rat_point& p</i> , <i>const rat_point& q</i>)	returns <i>p</i> reflected across the straight line passing through <i>p</i> and <i>q</i> .
<i>r_circle_point</i>	<i>p</i> .reflect(<i>const rat_point& p</i>)	returns <i>p</i> reflected across point <i>p</i> .
<i>bool</i>	<i>r_circle_point::</i> intersection(<i>const rat_circle& c</i> , <i>const rat_line& l</i> , <i>tag which</i> , <i>real_point& p</i>)	checks whether (<i>c</i> , <i>l</i> , <i>which</i>) is a valid triple, if so the corresponding point is assigned to the <i>real_point p</i> .
<i>bool</i>	<i>r_circle_point::</i> intersection(<i>const rat_circle& c</i> , <i>const rat_line& l</i> , <i>tag which</i> , <i>r_circle_point& p</i>)	same as above, except for the fact that <i>p</i> is of type <i>r_circle_point</i> .

15.28 Segment of Rational Circle (*r_circle_segment*)

1. Definition

An instance *cs* of type *r_circle_segment* is a segment of a rational circle (see Section 15.14), i.e. a circular arc. A segment is called *trivial* if it consists of a single point. A non-trivial instance *cs* is defined by two points *s* and *t* (of type *r_circle_point*) and an oriented circle *c* (of type *rat_circle*) such that *c* contains both *s* and *t*. We call *s* and *t* the *source* and the *target* of *cs*, and *c* is called its *supporting circle*. We want to point out that the circle may be a line, which means that *cs* is a straight line segment. An instance *cs* is called *degenerate*, if it is trivial or a straight line segment.

```
#include < LEDA/geo/r_circle_segment.h >
```

2. Creation

```
r_circle_segment cs; creates a trivial instance cs with source and target equal to the point (0,0).
```

```
r_circle_segment cs(const r_circle_point& src, const r_circle_point& tgt,  
const rat_circle& c);  
creates an instance cs with source src, target tgt and supporting  
circle c.  
Precondition: src ≠ tgt, c is not trivial and contains src and tgt.
```

```
r_circle_segment cs(const r_circle_point& src, const r_circle_point& tgt,  
const rat_line& l);  
creates an instance cs with source src, target tgt and supporting  
line l.  
Precondition: src ≠ tgt, l contains src and tgt.
```

```
r_circle_segment cs(const rat_point& src, const rat_point& middle, const rat_point& tgt);  
creates an instance cs with source src and target tgt which passes  
through middle.  
Precondition: the three points are distinct.
```

```
r_circle_segment cs(const r_circle_point& p);  
creates a trivial instance cs with source and target equal to p.
```

```
r_circle_segment cs(const rat_point& rat_pnt);  
creates a trivial instance cs with source and target equal to rat_pnt.
```

r_circle_segment *cs*(*const rat_circle& c*);

creates an instance *cs* which is equal to the full circle *c*.
Precondition: *c* is not degenerate.

r_circle_segment *cs*(*const rat_point& src, const rat_point& tgt*);

creates an instance *cs* which is equal to the straight line segment from *src* to *tgt*.

r_circle_segment *cs*(*const rat_segment& s*);

creates an instance *cs* which is equal to the straight line segment *s*.

r_circle_segment *cs*(*const r_circle_point& src, const r_circle_point& tgt*);

creates an instance *cs* which is equal to the straight line segment from *src* to *tgt*.

Precondition: Both *src* and *tgt* are *rat_points*.

3. Operations

void *cs.normalize*() simplifies the internal representation of *cs*.

const r_circle_point& *cs.source*() returns the source of *cs*.

const r_circle_point& *cs.target*() returns the target of *cs*.

const rat_circle& *cs.circle*() returns the supporting circle of *cs*.

rat_line *cs.supporting_line*() returns a line containing *cs*.
Precondition: *cs* is a straight line segment.

rat_point *cs.center*() returns the center of the supporting circle of *cs*.

int *cs.orientation*() returns the orientation (of the supporting circle) of *cs*.

real_point *cs.real_middle*() returns the middle point of *cs*, i.e. the intersection of *cs* and the bisector of its source and target.

r_circle_point *cs.middle*() returns a point on the circle of *cs*, which is close to *real_middle*().

bool *cs.is_trivial*() returns true iff *cs* is trivial.

bool *cs.is_degenerate*() returns true iff *cs* is degenerate.

bool *cs.is_full_circle*() returns true iff *cs* is a full circle.

bool *cs.is_proper_arc*() returns true iff *cs* is a proper arc, i.e. neither degenerate nor a full circle.

- bool* `cs.is_straight_segment()`
returns true iff *cs* is a straight line segment.
- bool* `cs.is_vertical_segment()`
returns true iff *cs* is a vertical straight line segment.
- bool* `cs.is_rat_segment()` returns true, if *cs* can be converted to *rat_segment*.
(The value false means “do not know”.)
- rat_segment* `cs.to_rat_segment()` converts *cs* to a *rat_segment*.
Precondition: *is_rat_segment* returns true.
- bool* `cs.contains(const r_circle_point& p)`
returns true iff *cs* contains *p*.
- bool* `cs.overlaps(const r_circle_segment& cs2)`
returns true iff *cs* (properly) overlaps *cs2*.
- bool* `cs.wedge_contains(const real_point& p)`
returns true iff the (closed) wedge induced by *cs* contains *p*. This wedge is spanned by the rays which start at the center and pass through source and target. (Note that *p* belongs to *cs* iff *p* is on the supporting circle and the wedge contains *p*.)
- r_circle_segment* `cs.reverse()` returns the reversal of *cs*, i.e. source and target are swapped and the supporting circle is reversed.
- r_circle_segment* `cs.round(int prec = 0)`
returns a rounded representation of *cs*. (experimental)
- r_circle_segment* `cs.translate(rational dx, rational dy)`
returns *cs* translated by vector (dx, dy) .
- r_circle_segment* `cs.translate(const rat_vector& v)`
returns *cs* translated by vector *v*.
- r_circle_segment* `cs + const rat_vector& v`
returns *cs* translated by vector *v*.
- r_circle_segment* `cs - const rat_vector& v`
returns *cs* translated by vector $-v$.
- r_circle_segment* `cs.rotate90(const rat_point& q, int i = 1)`
returns *cs* rotated about *q* by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

- r_circle_segment* *cs*.reflect(*const rat_point& p*, *const rat_point& q*)
 returns *cs* reflected across the straight line passing through *p* and *q*.
- r_circle_segment* *cs*.reflect(*const rat_point& p*)
 returns *cs* reflected across point *p*.
- list<r_circle_point>* *cs*.intersection(*const rat_line& l*)
 computes $cs \cap l$ (ordered along *l*).
- list<real_point>* *cs*.intersection(*const real_line& l*)
 as above.
- list<r_circle_point>* *cs*.intersection(*const rat_circle& c*)
 computes $cs \cap c$ (ordered lexicographically).
- list<r_circle_point>* *cs*.intersection(*const r_circle_segment& cs2*)
 computes $cs \cap cs2$ (ordered lexicographically).
- real* *cs*.sqr_dist(*const real_point& p*)
 computes the squared Euclidean distance between *cs* and *p*.
- real* *cs*.dist(*const real_point& p*)
 computes the euclidean distance between *cs* and *p*.
- real_line* *cs*.tangent_at(*const r_circle_point& p*)
 computes the tangent to *cs* at *p*.
Precondition: *cs* is not trivial.
- double* *cs*.approximate_area()
 computes the (oriented) area enclosed by the convex hull of *cs*.
- void* *cs*.compute_bounding_box(*real& xmin*, *real& ymin*, *real& xmax*,
real& ymax)
 computes a tight bounding box for *cs*.
- list<point>* *cs*.approximate(*double dist*)
 approximates *cs* by a sequence of points. Connecting the points with straight line segments yields a chain with the following property: The maximum distance from a point on *cs* to the chain is bounded by *dist*.
- list<rat_point>* *cs*.approximate_by_rat_points(*double dist*)
 as above, returns *rat_points* instead of *points*.

list<rat_segment> *cs*.*approximate_by_rat_segments(double dist)*

approximates *cs* by a chain of *rat_segments*. The maximum distance from a point on *cs* to the chain is bounded by *dist*.

bool *equal_as_sets(const r_circle_segment& cs1, const r_circle_segment& cs2)*

returns whether *cs1* and *cs2* describe the same set of points.

int *compare_tangent_slopes(const r_circle_segment& cs1,*
const r_circle_segment& cs2,
const r_circle_point& p)

compares the slopes of the tangents to *cs1* and *cs2* in the point *p*.

Precondition: *cs1* and *cs2* contain *p*.

We provide the operator << to display an instance *cs* of type *r_circle_segment* in a *window* and the operator >> for reading *cs* from a *window* (see *real_window.h*).

void *SWEEP_SEGMENTS(const list<r_circle_segment>& L,*
GRAPH<r_circle_point, r_circle_segment>& G,
bool embed = true)

takes as input a list *L* of *r_circle_segments* and computes the planar graph *G* induced by the segments in *L*. The nodes of *G* are all endpoints and all proper intersection points of segments in *L*. The edges of *G* are the maximal relatively open subsegments of segments in *L* that contain no node of *G*. The edges are directed as the corresponding segments, if *embed* is false. Otherwise, the corresponding planar map is computed. Note that for each edge *e* *G*[*e*] is the input segment containing *e*.

The algorithm (a variant of [11]) runs in time $O((n + s) \log n + m)$, where *n* is the number of segments, *s* is the number of vertices of the graph *G*, and *m* is the number of edges of *G*. If *L* contains no overlapping segments then $m = O(n + s)$.

15.29 Polygons with circular edges (`r_circle_polygon`)

1. Definition

An instance P of the data type `r_circle_polygon` is a cyclic list of `r_circle_segments`, i.e. straight line or circular segments. A polygon is called *simple* if all nodes of the graph induced by its segments have degree two and it is called *weakly simple*, if its segments are disjoint except for common endpoints and if the chain does not cross itself. See the LEDA book for details.

A weakly simple polygon splits the plane into an unbounded region and one or more bounded regions. For a simple polygon there is just one bounded region. When a weakly simple polygon P is traversed either the bounded region is consistently to the left of P or the unbounded region is consistently to the left of P . We say that P is positively oriented in the former case and negatively oriented in the latter case. We use P to also denote the region to the left of P and call this region the positive side of P .

The number of segments is called the *size* of P . A polygon of size zero is *trivial*; it either describes the empty set or the full two-dimensional plane.

```
#include < LEDA/geo/r_circle_polygon.h >
```

2. Types

```
r_circle_polygon::coord_type
```

the coordinate type (*real*).

```
r_circle_polygon::point_type
```

the point type (`r_circle_point`).

```
r_circle_polygon::segment_type
```

the segment type (`r_circle_segment`).

```
r_circle_polygon::KIND { EMPTY, FULL, NON_TRIVIAL }
```

describes the kind of the polygon: the empty set, the full plane or a non-trivial polygon.

```
r_circle_polygon::CHECK_TYPE { NO_CHECK, SIMPLE, WEAKLY_SIMPLE, NOT_WEAKLY_SIMPLE }
```

used to specify which checks should be applied and also describes the outcome of a simplicity check.

r_circle_polygon:: *RESPECT_TYPE* { *DISREGARD_ORIENTATION*, *RESPECT_ORIENTATION* }

used in constructors to specify whether to force a positive orientation for the constructed object (*DISREGARD_ORIENTATION*) or to keep the orientation of the input (*RESPECT_ORIENTATION*).

3. Creation

r_circle_polygon *P*; creates an empty polygon *P*.

r_circle_polygon *P*(*KIND* *k*);
creates a polygon *P* of kind *k*, where *k* is either *EMPTY* or *FULL*.

r_circle_polygon *P*(*const list*<*r_circle_segment*>& *chain*,
CHECK_TYPE *check* = *WEAKLY_SIMPLE*,
RESPECT_TYPE *respect_orient* = *RESPECT_ORIENTATION*);
creates a polygon *P* from a closed chain of segments.

r_circle_polygon *P*(*const list*<*rat_point*>& *L*,
CHECK_TYPE *check* = *WEAKLY_SIMPLE*,
RESPECT_TYPE *respect_orient* = *RESPECT_ORIENTATION*);
creates a polygon *P* with straight line edges from a list *L* of vertices.

r_circle_polygon *P*(*const rat_polygon*& *Q*, *CHECK_TYPE* *check* = *NO_CHECK*,
RESPECT_TYPE *respect_orient* = *RESPECT_ORIENTATION*);
converts a *rat_polygon* *Q* to an *r_circle_polygon* *P*.

r_circle_polygon *P*(*const polygon*& *Q*, *CHECK_TYPE* *check* = *NO_CHECK*,
RESPECT_TYPE *respect_orient* = *RESPECT_ORIENTATION*,
int *prec* = *rat_point*::*default_precision*);
converts the (floating point) *polygon* *Q* to an *r_circle_polygon*. *P* is initialized to a rational approximation of *Q* of coordinates with denominator at most *prec*. If *prec* is zero, the implementation chooses *prec* large enough such that there is no loss of precision in the conversion.

r_circle_polygon *P*(*const rat_circle*& *circ*,
RESPECT_TYPE *respect_orient* = *RESPECT_ORIENTATION*);
creates a polygon *P* whose boundary is the circle *circ*.

4. Operations

KIND *P.kind*() returns the kind of *P*.

bool *P.is_trivial*() returns true iff *P* is trivial.

bool *P.is_empty*() returns true iff *P* is empty.

- bool* *P.is_full()* returns true iff *P* is the full plane.
- void* *P.normalize()* simplifies the representation by calling *s.normalize()* for every segment *s* of *P*.
- bool* *P.is_closed_chain()* tests whether *P* is a closed chain.
- bool* *P.is_simple()* tests whether *P* is simple.
- bool* *P.is_weakly_simple()* tests whether *P* is weakly simple.
- bool* *P.is_weakly_simple(list<r_circle_point>& crossings)*
as above, returns all proper points of intersection in *crossings*.
- CHECK_TYPE P.check_simplicity()*
checks *P* for simplicity. The result can be *SIMPLE*, *WEAKLY_SIMPLE* or *NOT_WEAKLY_SIMPLE*.
- bool* *P.is_convex()* returns true iff *P* is convex.
- int* *P.size()* returns the size of *P*.
- const list<r_circle_segment>& P.segments()*
returns a chain of segments that bound *P*. The orientation of the chain corresponds to the orientation of *P*.
- list<r_circle_point> P.vertices()* returns the vertices of *P*.
- list<r_circle_point> P.intersection(const r_circle_segment& s)*
returns the list of all proper intersections between *s* and the boundary of *P*.
- list<r_circle_point> P.intersection(const rat_line& l)*
returns the list of all proper intersections between *l* and the boundary of *P*.
- r_circle_polygon P.intersection_halfplane(const rat_line& l)*
clips *P* against the halfplane on the positive side of *l*. Observe that the result is only guaranteed to be weakly simple if *P* is convex.
- r_circle_polygon P.translate(rational dx, rational dy)*
returns *P* translated by vector (dx, dy) .
- r_circle_polygon P.translate(const rat_vector& v)*
returns *P* translated by vector *v*.

r_circle_polygon $P + \text{const rat_vector\& } v$

returns P translated by vector v .

r_circle_polygon $P - \text{const rat_vector\& } v$

returns P translated by vector $-v$.

r_circle_polygon $P.\text{rotate90}(\text{const rat_point\& } q, \text{int } i = 1)$

returns P rotated about q by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.

r_circle_polygon $P.\text{reflect}(\text{const rat_point\& } p, \text{const rat_point\& } q)$

returns P reflected across the straight line passing through p and q .

r_circle_polygon $P.\text{reflect}(\text{const rat_point\& } p)$

returns P reflected across point p .

real $P.\text{sqr_dist}(\text{const real_point\& } p)$

computes the squared Euclidean distance between the boundary of P and p . (If P is zero, the result is zero.)

real $P.\text{dist}(\text{const real_point\& } p)$

computes the Euclidean distance between the boundary of P and p . (If P is zero, the result is zero.)

list<r_circle_polygon> $P.\text{split_into_weakly_simple_parts}()$

splits P into a set of weakly simple polygons whose union coincides with the inner points of P . (This function is experimental.)

r_circle_gen_polygon $P.\text{make_weakly_simple}()$

creates a weakly simple generalized polygon Q from a possibly non-simple polygon P such that Q and P have the same inner points. (This function is experimental.)

r_circle_polygon $P.\text{complement}()$ returns the complement of P .

r_circle_polygon $P.\text{eliminate_cocircular_vertices}()$

returns a copy of P without cocircular vertices.

r_circle_polygon $P.\text{round}(\text{int } \textit{prec} = 0)$

returns a rounded representation of P . (experimental)

bool $P.\text{is_rat_polygon}()$

returns whether P can be converted to a *rat_polygon*.

<i>rat_polygon</i>	<i>P.to_rat_polygon()</i>	converts <i>P</i> to a <i>rat_polygon</i> . Precondition: <i>is_rat_polygon</i> is true.
<i>rat_polygon</i>	<i>P.approximate_by_rat_polygon(double dist)</i>	approximates <i>P</i> by a <i>rat_polygon</i> . The maximum distance between a point on <i>P</i> and the approximation is bounded by <i>dist</i> .
<i>polygon</i>	<i>P.to_float()</i>	computes a floating point approximation of <i>P</i> with straight line segments. Precondition: <i>is_rat_polygon</i> is true.
<i>bool</i>	<i>P.is_rat_circle()</i>	returns whether <i>P</i> can be converted to a <i>rat_circle</i> .
<i>rat_circle</i>	<i>P.to_rat_circle()</i>	converts <i>P</i> to a <i>rat_circle</i> . Precondition: <i>is_rat_circle</i> is true.
<i>void</i>	<i>P.bounding_box(real& xmin, real& ymin, real& xmax, real& ymax)</i>	computes a tight bounding box for <i>P</i> .
<i>void</i>	<i>P.bounding_box(double& xmin, double& ymin, double& xmax, double& ymax)</i>	computes a bounding box for <i>P</i> , but not necessarily a tight one.

All functions below assume that *P* is weakly simple.

<i>int</i>	<i>P.orientation()</i>	returns the orientation of <i>P</i> .
<i>int</i>	<i>P.side_of(const r_circle_point& p)</i>	returns +1 if <i>p</i> lies to the left of <i>P</i> , 0 if <i>p</i> lies on <i>P</i> , and -1 if <i>p</i> lies to the right of <i>P</i> .
<i>region_kind</i>	<i>P.region_of(const r_circle_point& p)</i>	returns BOUNDED_REGION if <i>p</i> lies in the bounded region of <i>P</i> , returns ON_REGION if <i>p</i> lies on <i>P</i> , and returns UNBOUNDED_REGION if <i>p</i> lies in the unbounded region.
<i>bool</i>	<i>P.inside(const r_circle_point& p)</i>	returns true if <i>p</i> lies to the left of <i>P</i> , i.e., <i>side_of(p) == +1</i> .
<i>bool</i>	<i>P.on_boundary(const r_circle_point& p)</i>	returns true if <i>p</i> lies on <i>P</i> , i.e., <i>side_of(p) == 0</i> .
<i>bool</i>	<i>P.outside(const r_circle_point& p)</i>	returns true if <i>p</i> lies to the right of <i>P</i> , i.e., <i>side_of(p) == -1</i> .

bool *P.contains(const r_circle_point& p)*

returns true if *p* lies to the left of or on *P*.

double *P.approximate_area()*

approximates the (oriented) area of the bounded region of *P*.

Precondition: P.kind() is not full.

r_circle_gen_polygon *buffer(double d)*

adds an exterior buffer zone to *P* (if $d > 0$), or removes an interior buffer zone from *P* (if $d < 0$). More precisely, for $d \geq 0$ define the buffer tube *T* as the set of all points in the complement of *P* whose distance to *P* is at most *d*. Then the function returns $P \cup T$. For $d < 0$ let *T* denote the set of all points in *P* whose distance to the complement is less than $|d|$. Then the result is $P \setminus T$. *Note* that the result is a generalized polygon since the buffer of a connected polygon may be disconnected, i.e. consist of several parts, if $d < 0$.

Iterations Macros

forall_vertices(*v, P*) { “the vertices of *P* are successively assigned to *r_circle_point v*” }

forall_segments(*s, P*) { “the edges of *P* are successively assigned to the segment *s*” }

15.30 Generalized polygons with circular edges (`r_circle_gen_polygon`)

1. Definition

The data type `r_circle_polygon` is not closed under boolean operations, e.g., the set difference of a polygon P and a polygon Q nested in P is a region that contains a “hole”. Therefore we provide a generalization called `r_circle_gen_polygon` which is closed under (regularized) boolean operations (see below).

A formal definition follows: An instance P of the data type `r_circle_gen_polygon` is a regular polygonal region in the plane. A regular region is an open set that is equal to the interior of its closure. A region is polygonal if its boundary consists of a finite number of `r_circle_segments`.

The boundary of an `r_circle_gen_polygon` consists of zero or more weakly simple closed polygonal chains. Each such chain is represented by an object of type `r_circle_ploygon`. There are two regions whose boundary is empty, namely the *empty region* and the *full region*. The full region encompasses the entire plane. We call a region *trivial* if its boundary is empty. The boundary cycles P_1, P_2, \dots, P_k of an `r_circle_gen_polygon` are ordered such that no P_i is nested in a P_j with $i < j$.

```
#include < LEDA/geo/r_circle_gen_polygon.h >
```

2. Types

```
r_circle_gen_polygon::coord_type
```

the coordinate type (*real*).

```
r_circle_gen_polygon::point_type
```

the point type (`r_circle_point`).

```
r_circle_gen_polygon::segment_type
```

the segment type (`r_circle_segment`).

```
r_circle_gen_polygon::polygon_type
```

the polygon type (`r_circle_polygon`).

```
r_circle_gen_polygon::KIND { EMPTY, FULL, NON_TRIVIAL }
```

describes the kind of the polygon: the empty set, the full plane or a non-trivial polygon.

```
r_circle_gen_polygon::CHECK_TYPE { NO_CHECK, SIMPLE, WEAKLY_SIMPLE, NOT  
_WEAKLY_SIMPLE }
```

used to specify which checks should be applied and also describes the outcome of a simplicity check.

r_circle_gen_polygon:: *RESPECT_TYPE* { *DISREGARD_ORIENTATION*, *RESPECT_ORIENTATION* }

used in constructors to specify whether to force a positive orientation for the constructed object (*DISREGARD_ORIENTATION*) or to keep the orientation of the input (*RESPECT_ORIENTATION*).

3. Creation

r_circle_gen_polygon *P*;

creates an empty polygon *P*.

r_circle_gen_polygon *P*(*KIND* *k*);

creates a polygon *P* of kind *k*, where *k* is either *EMPTY* or *FULL*.

r_circle_gen_polygon *P*(*const list*<*r_circle_segment*>& *seg_chain*,
CHECK_TYPE *check* = *WEAKLY_SIMPLE*,
RESPECT_TYPE *respect_orient* =
RESPECT_ORIENTATION);

creates a polygon *P* from a single closed chain of segments.

r_circle_gen_polygon *P*(*const r_circle_polygon*& *Q*,
CHECK_TYPE *check* = *NO_CHECK*,
RESPECT_TYPE *respect_orient* =
RESPECT_ORIENTATION);

converts an *r_circle_polygon* *Q* to an *r_circle_gen_polygon* *P*.

r_circle_gen_polygon *P*(*const list*<*rat_point*>& *L*,
CHECK_TYPE *check* = *NO_CHECK*,
RESPECT_TYPE *respect_orient* =
RESPECT_ORIENTATION);

creates a polygon *P* with straight line edges from a list *L* of vertices.

r_circle_gen_polygon *P*(*const list*<*r_circle_polygon*>& *polys*,
CHECK_TYPE *check* = *NO_CHECK*,
RESPECT_TYPE *respect_orient* =
RESPECT_ORIENTATION);

introduces a variable *P* of type *r_circle_gen_polygon*. *P* is initialized to the polygon with boundary representation *polys*.

Precondition: *polys* must be a boundary representation.

r_circle_gen_polygon *P*(*const list*<*r_circle_gen_polygon*>& *gen_polys*);

creates a polygon *P* as the union of all the polygons in *gen_polys*.

Precondition: Every polygon in *gen_polys* must be weakly simple.

r_circle_gen_polygon $P(\text{const rat_gen_polygon}\& Q,$
CHECK_TYPE *check* = *NO_CHECK*,
RESPECT_TYPE *respect_orient* =
RESPECT_ORIENTATION);
 converts a *rat_gen_polygon* Q to an *r_circle_gen_polygon* P .

r_circle_gen_polygon $P(\text{const gen_polygon}\& Q,$ *CHECK_TYPE* *check* = *NO_CHECK*,
RESPECT_TYPE *respect_orient* =
RESPECT_ORIENTATION,
int prec = *rat_point::default_precision*);
 converts the (floating point) *gen_polygon* Q to an
r_circle_gen_polygon. P is initialized to a rational approxima-
 tion of Q of coordinates with denominator at most *prec*. If *prec*
 is zero, the implementation chooses *prec* large enough such that
 there is no loss of precision in the conversion.

r_circle_gen_polygon $P(\text{const rat_circle}\& \textit{circ},$ *RESPECT_TYPE* *respect_orient* =
RESPECT_ORIENTATION);
 creates a polygon P whose boundary is the circle *circ*.

4. Operations

<i>KIND</i>	$P.\textit{kind}()$	returns the kind of P .
<i>bool</i>	$P.\textit{is_trivial}()$	returns true iff P is trivial.
<i>bool</i>	$P.\textit{is_empty}()$	returns true iff P is empty.
<i>bool</i>	$P.\textit{is_full}()$	returns true iff P is full.
<i>void</i>	$P.\textit{normalize}()$	simplifies the representation by calling <i>c.normalize()</i> for every polygonal chain c of P .
<i>bool</i>	$P.\textit{is_simple}()$	tests whether P is simple or not.
<i>bool</i>	$P.\textit{is_weakly_simple}()$	tests whether P is weakly simple or not.
<i>bool</i>	$P.\textit{is_weakly_simple}(\textit{list}\langle\textit{r_circle_point}\rangle\& \textit{crossings})$	as above, returns all proper points of intersection in <i>crossings</i> .
<i>bool</i>	$\textit{r_circle_gen_polygon}::\textit{check_representation}(\textit{const list}\langle\textit{r_circle_polygon}\rangle\& \textit{polys},$ <i>CHECK_TYPE</i> <i>check</i> = <i>WEAKLY_SIMPLE</i>)	checks whether <i>polys</i> is a boundary representation. Currently the nesting order is not checked, we check only for (weak) simplicity.

- bool* P .check_representation()
checks the representation of P (see above).
- bool* P .is_convex()
returns true iff P is convex.
- int* P .size()
returns the size of P , i.e. the number of segments in its boundary representation.
- const list<r_circle_polygon>&* P .polygons()
returns the boundary representation of P .
- list<r_circle_segment>* P .edges()
returns a chain of segments that bound P . The orientation of the chain corresponds to the orientation of P .
- list<r_circle_point>* P .vertices()
returns the vertices of P .
- list<r_circle_point>* P .intersection(*const r_circle_segment& s*)
returns the list of all proper intersections between s and the boundary of P .
- list<r_circle_point>* P .intersection(*const rat_line& l*)
returns the list of all proper intersections between l and the boundary of P .
- r_circle_gen_polygon* P .translate(*rational dx, rational dy*)
returns P translated by vector (dx, dy) .
- r_circle_gen_polygon* P .translate(*const rat_vector& v*)
returns P translated by vector v .
- r_circle_gen_polygon* $P + \text{const rat_vector\& } v$
returns P translated by vector v .
- r_circle_gen_polygon* $P - \text{const rat_vector\& } v$
returns P translated by vector $-v$.
- r_circle_gen_polygon* P .rotate90(*const rat_point& q, int i = 1*)
returns P rotated about q by an angle of $i \times 90$ degrees. If $i > 0$ the rotation is counter-clockwise otherwise it is clockwise.
- r_circle_gen_polygon* P .reflect(*const rat_point& p, const rat_point& q*)
returns P reflected across the straight line passing through p and q .
- r_circle_gen_polygon* P .reflect(*const rat_point& p*)
returns P reflected across point p .

- real* *P*.sqr_dist(*const real_point*& *p*)
 computes the squared Euclidean distance between the boundary of *P* and *p*. (If *P* is zero, the result is zero.)
- real* *P*.dist(*const real_point*& *p*)
 computes the Euclidean distance between the boundary of *P* and *p*. (If *P* is zero, the result is zero.)
- r_circle_gen_polygon* *P*.make_weakly_simple()
 creates a weakly simple generalized polygon *Q* from a possibly non-simple polygon *P* such that *Q* and *P* have the same inner points. (This function is experimental.)
- r_circle_gen_polygon r_circle_gen_polygon* :: make_weakly_simple(*const r_circle_polygon*& *Q*)
 same as above, but the input is a polygon *Q*. (This function is experimental.)
- r_circle_gen_polygon* *P*.complement()
 returns the complement of *P*.
- r_circle_gen_polygon* *P*.contour()
 returns the contour of *P*, i.e. all holes are removed from *P*.
- r_circle_gen_polygon* *P*.eliminate_cocircular_vertices()
 returns a copy of *P* without cocircular vertices.
- r_circle_gen_polygon* *P*.round(*int prec* = 0)
 returns a rounded representation of *P*. (experimental)
- bool* *P*.is_r_circle_polygon()
 checks if the boundary of *P* consists of at most one chain.
- r_circle_polygon* *P*.to_r_circle_polygon()
 converts *P* to an *r_circle_polygon*.
Precondition: *is_r_circle_polygon* is true.
- bool* *P*.is_rat_gen_polygon()
 returns whether *P* can be converted to a *rat_polygon*.
- rat_gen_polygon* *P*.to_rat_gen_polygon()
 converts *P* to a *rat_gen_polygon*.
Precondition: *is_rat_gen_polygon* is true.
- rat_gen_polygon* *P*.approximate_by_rat_gen_polygon(*double dist*)
 approximates *P* by a *rat_gen_polygon*. The maximum distance between a point on *P* and the approximation is bounded by *dist*.

<i>gen_polygon</i>	<i>P.to_float()</i>	computes a floating point approximation of <i>P</i> with straight line segments. <i>Precondition: is_rat_gen_polygon</i> is true.
<i>bool</i>	<i>P.is_rat_circle()</i>	returns whether <i>P</i> can be converted to a <i>rat_circle</i> .
<i>rat_circle</i>	<i>P.to_rat_circle()</i>	converts <i>P</i> to a <i>rat_circle</i> . <i>Precondition: is_rat_circle</i> is true.
<i>void</i>	<i>P.bounding_box(real& xmin, real& ymin, real& xmax, real& ymax)</i>	computes a tight bounding box for <i>P</i> .
<i>void</i>	<i>P.bounding_box(double& xmin, double& ymin, double& xmax, double& ymax)</i>	computes a bounding box for <i>P</i> , but not necessarily a tight one.

All functions below assume that *P* is weakly simple.

<i>int</i>	<i>P.orientation()</i>	returns the orientation of <i>P</i> .
<i>int</i>	<i>P.side_of(const r_circle_point& p)</i>	returns +1 if <i>p</i> lies to the left of <i>P</i> , 0 if <i>p</i> lies on <i>P</i> , and -1 if <i>p</i> lies to the right of <i>P</i> .
<i>region_kind</i>	<i>P.region_of(const r_circle_point& p)</i>	returns BOUNDED_REGION if <i>p</i> lies in the bounded region of <i>P</i> , returns ON_REGION if <i>p</i> lies on <i>P</i> , and returns UNBOUNDED_REGION if <i>p</i> lies in the unbounded region. The bounded region of the full polygon is the entire plane.
<i>bool</i>	<i>P.inside(const r_circle_point& p)</i>	returns true if <i>p</i> lies to the left of <i>P</i> , i.e., <i>side_of(p) == +1</i> .
<i>bool</i>	<i>P.on_boundary(const r_circle_point& p)</i>	returns true if <i>p</i> lies on <i>P</i> , i.e., <i>side_of(p) == 0</i> .
<i>bool</i>	<i>P.outside(const r_circle_point& p)</i>	returns true if <i>p</i> lies to the right of <i>P</i> , i.e., <i>side_of(p) == -1</i> .
<i>bool</i>	<i>P.contains(const r_circle_point& p)</i>	returns true if <i>p</i> lies to the left of or on <i>P</i> .

double P .approximate_area()

approximates the (oriented) area of the bounded region of P .

Precondition: $P.kind()$ is not full.

All boolean operations are regularized, i.e., the result R of the standard boolean operation is replaced by the interior of the closure of R . We use $\text{reg } X$ to denote the regularization of a set X .

r_circle_gen_polygon P .unite(const *r_circle_gen_polygon*& Q)

returns $\text{reg}(P \cup Q)$.

r_circle_gen_polygon P .intersection(const *r_circle_gen_polygon*& Q)

returns $\text{reg}(P \cap Q)$.

r_circle_gen_polygon P .diff(const *r_circle_gen_polygon*& Q)

returns $\text{reg}(P \setminus Q)$.

r_circle_gen_polygon P .sym_diff(const *r_circle_gen_polygon*& Q)

returns $\text{reg}((P \cup Q) - (P \cap Q))$.

For optimization purposes we provide a union operation of arbitrary arity. It computes the union of a set of polygons much faster than with binary operations.

r_circle_gen_polygon *r_circle_gen_polygon*::unite(const list<*r_circle_gen_polygon*>& L)

returns the (regularized) union of all polygons in L .

We offer fast versions of the boolean operations which compute an approximate result. These operations work as follows: every curved segment is approximated by straight line segments, then the respective boolean operation is performed on the straight polygons. Finally, we identify those straight segments in the result that originate from a curved segment and replace them by curved segments again. (We denote the approximate computation of an operation op scheme by $\text{appr}(op)$.) Every operation below takes a parameter $dist$ that controls the accuracy of the approximation: $dist$ is an upper bound on the distance of any point on an original polygon P to the approximated polygon P' .

r_circle_gen_polygon P .unite_approximate(const *r_circle_gen_polygon*& Q ,

double $dist = 1e - 2$)

returns $\text{appr}(P \cup Q)$.

r_circle_gen_polygon P .intersection_approximate(const *r_circle_gen_polygon*& Q ,

double $dist = 1e - 2$)

returns $\text{appr}(P \cap Q)$.

r_circle_gen_polygon P .diff_approximate(const *r_circle_gen_polygon*& Q ,

double $dist = 1e - 2$)

returns $\text{appr}(P \setminus Q)$.

r_circle_gen_polygon *P*.sym_diff_approximate(*const r_circle_gen_polygon*& *Q*,
double *dist* = $1e-2$)
returns $\text{appr}((P \cup Q) - (P \cap Q))$.

r_circle_gen_polygon *r_circle_gen_polygon::*unite_approximate(*const list<r_circle_gen_polygon>*& *L*,
double *dist* = $1e-2$)
returns the (approximated) union of all polygons in
L.

r_circle_gen_polygon *P*.buffer(*double d*)

adds an exterior buffer zone to P ($d > 0$), or removes an interior buffer zone from P ($d < 0$). More precisely, for $d \geq 0$ define the buffer tube T as the set of all points in the complement of P whose distance to P is at most d . Then the function returns $P \cup T$. For $d < 0$ let T denote the set of all points in P whose distance to the complement is less than $|d|$. Then the result is $P \setminus T$.

Iterations Macros

forall_polygons(*p, P*) { “the boundary polygons of P are successively assigned to
r_circle_polygon p” }

15.31 Parser for well known binary format (`wkb_io`)

1. Definition

The class `wkb_io` provides methods for reading and writing geometries in the well known binary format (wkb). Every non-trivial generalized polygon from LEDA can be written in wkb format. The method for reading supports the wkb types `Polygon` and `MultiPolygon`, i.e., those types that can be represented by the LEDA type `gen_polygon`.

```
#include < LEDA/geo/wkb_io.h >
```

2. Creation

```
wkb_io W;                creates an instance of type wkb_io.
```

3. Operations

```
bool          W.read(const string& filename, gen_polygon& P)  
                                                 reads the geometry stored in the given file and converts it to a generalized polygon P.
```

```
bool          W.write(const string& filename, const gen_polygon& P)  
                                                 writes the generalized polygon P to the given file.
```

Chapter 16

Advanced Data Types for Two-Dimensional Geometry

16.1 Two-Dimensional Dictionaries (`d2_dictionary`)

1. Definition

An instance D of the parameterized data type $d2_dictionary\langle K1, K2, I \rangle$ is a collection of items ($dic2_item$). Every item in D contains a key from the linearly ordered data type $K1$, a key from the linearly ordered data type $K2$, and an information from data type I . $K1$ and $K2$ are called the key types of D , and I is called the information type of D . If $K1$ resp. $K2$ are user-defined types, you have to provide a compare function for type $K1$ resp. $K2$ (see Section 2.3). The number of items in D is called the size of D . A two-dimensional dictionary of size zero is said to be empty. We use $\langle k_1, k_2, i \rangle$ to denote the item with first key k_1 , second key k_2 , and information i . For each pair $(k_1, k_2) \in K1 \times K2$ there is at most one item $\langle k_1, k_2, i \rangle \in D$. Additionally to the normal dictionary operations, the data type $d2_dictionary$ supports rectangular range queries on $K1 \times K2$.

```
#include < LEDA/geo/d2_dictionary.h >
```

2. Creation

```
 $d2\_dictionary\langle K1, K2, I \rangle D$ ;
```

creates an instance D of type $d2_dictionary\langle K1, K2, I \rangle$ and initializes D to the empty dictionary.

3. Operations

```
const  $K1\&$      $D.key1(dic2\_item\ it)$     returns the first key of item  $it$ .  
                                           Precondition:  $it$  is an item in  $D$ .  
  
const  $K2\&$      $D.key2(dic2\_item\ it)$     returns the second key of item  $it$ .  
                                           Precondition:  $it$  is an item in  $D$ .
```

<i>const I&</i>	<i>D.inf(dic2_item it)</i>	returns the information of item <i>it</i> . <i>Precondition: it</i> is an item in <i>D</i> .
<i>I&</i>	<i>D[dic2_item it]</i>	returns a reference to the information of item <i>it</i> . <i>Precondition: it</i> is an item in <i>D</i> .
<i>dic2_item</i>	<i>D.min_key1()</i>	returns the item with minimal first key.
<i>dic2_item</i>	<i>D.min_key2()</i>	returns the item with minimal second key.
<i>dic2_item</i>	<i>D.max_key1()</i>	returns the item with maximal first key.
<i>dic2_item</i>	<i>D.max_key2()</i>	returns the item with maximal second key.
<i>dic2_item</i>	<i>D.insert(const K1& x, const K2& y, const I& i)</i>	associates the information <i>i</i> with the keys <i>x</i> and <i>y</i> . If there is an item $\langle x, y, j \rangle$ in <i>D</i> then <i>j</i> is replaced by <i>i</i> , else a new item $\langle x, y, i \rangle$ is added to <i>D</i> . In both cases the item is returned.
<i>dic2_item</i>	<i>D.lookup(const K1& x, const K2& y)</i>	returns the item with keys <i>x</i> and <i>y</i> (nil if no such item exists in <i>D</i>).
<i>list<dic2_item></i>	<i>D.range_search(const K1& x0, const K1& x1, const K2& y0, const K2& y1)</i>	returns the list of all items $\langle k_1, k_2, i \rangle$ in <i>D</i> with $x_0 \leq k_1 \leq x_1$ and $y_0 \leq k_2 \leq y_1$.
<i>list<dic2_item></i>	<i>D.allItems()</i>	returns the list of all items of <i>D</i> .
<i>void</i>	<i>D.del(const K1& x, const K2& y)</i>	deletes the item with keys <i>x</i> and <i>y</i> from <i>D</i> .
<i>void</i>	<i>D.deLitem(dic2_item it)</i>	removes item <i>it</i> from <i>D</i> . <i>Precondition: it</i> is an item in <i>D</i> .
<i>void</i>	<i>D.change_inf(dic2_item it, const I& i)</i>	makes <i>i</i> the information of item <i>it</i> . <i>Precondition: it</i> is an item in <i>D</i> .
<i>void</i>	<i>D.clear()</i>	makes <i>D</i> the empty d2_dictionary.
<i>bool</i>	<i>D.empty()</i>	returns true if <i>D</i> is empty, false otherwise.
<i>int</i>	<i>D.size()</i>	returns the size of <i>D</i> .

4. Implementation

Two-dimensional dictionaries are implemented by dynamic two-dimensional range trees [90, 57] based on BB[α] trees. Operations `insert`, `lookup`, `del_item`, `del` take time $O(\log^2 n)$, `range_search` takes time $O(k + \log^2 n)$, where k is the size of the returned list, `key`, `inf`, `empty`, `size`, `change_inf` take time $O(1)$, and `clear` takes time $O(n \log n)$. Here n is the current size of the dictionary. The space requirement is $O(n \log n)$.

16.2 Point Sets and Delaunay Triangulations (POINT_SET)

1. Definition

There are three instantiations of *POINT_SET*: *point_set* (floating point kernel), *rat_point_set* (rational kernel) and *real_point_set* (real kernel). The respective header file name corresponds to the type name (with “.h” appended).

An instance T of data type *POINT_SET* is a planar embedded bidirected graph (map) representing the *Delaunay Triangulation* of its vertex set. The position of a vertex v is given by $T.pos(v)$ and we use $S = \{T.pos(v) \mid v \in T\}$ to denote the underlying point set. Each face of T (except for the outer face) is a triangle whose circumscribing circle does not contain any point of S in its interior. For every edge e , the sequence

$$e, T.face_cycle_succ(e), T.face_cycle_succ(T.face_cycle_succ(e)), \dots$$

traces the boundary of the face to the left of e . The edges of the outer face of T form the convex hull of S ; the trace of the convex hull is clockwise. The subgraph obtained from T by removing all diagonals of co-circular quadrilaterals is called the *Delaunay Diagram* of S .

POINT_SET provides all *constant* graph operations, e.g., $T.reversal(e)$ returns the reversal of edge e , $T.all_edges()$ returns the list of all edges of T , and $forall_edges(e, T)$ iterates over all edges of T . In addition, *POINT_SET* provides operations for inserting and deleting points, point location, nearest neighbor searches, and navigation in both the triangulation and the diagram.

*POINT_SET*s are essentially objects of type $GRAPH<POINT, int>$, where the node information is the position of the node and the edge information is irrelevant. For a graph G of type $GRAPH<POINT, int>$ the function $Is_Delaunay(G)$ tests whether G is a Delaunay triangulation of its vertices.

The data type *POINT_SET* is illustrated by the *point_set_demo* in the LEDA demo directory.

Be aware that the nearest neighbor queries for a point (not for a node) and the range search queries for circles, triangles, and rectangles are non-const operations and modify the underlying graph. The set of nodes and edges is not changed; however, it is not guaranteed that the underlying Delaunay triangulation is unchanged.

```
#include < LEDA/geo/generic/POINT_SET.h >
```

2. Creation

```
POINT_SET T;      creates an empty POINT_SET T.
```

POINT_SET $T(\text{const list}\langle\text{POINT}\rangle\& S);$

creates a *POINT_SET* T of the points in S . If S contains multiple occurrences of points only the last occurrence of each point is retained.

POINT_SET $T(\text{const GRAPH}\langle\text{POINT}, \text{int}\rangle\& G);$

initializes T with a copy of G .

Precondition: $Is_Delaunay(G)$ is true.

3. Operations

void $T.\text{init}(\text{const list}\langle\text{POINT}\rangle\& L)$

makes T a *POINT_SET* for the points in S .

POINT $T.\text{pos}(\text{node } v)$

returns the position of node v .

POINT $T.\text{pos_source}(\text{edge } e)$

returns the position of $\text{source}(e)$.

POINT $T.\text{pos_target}(\text{edge } e)$

returns the position of $\text{target}(e)$.

SEGMENT $T.\text{seg}(\text{edge } e)$

returns the line segment corresponding to edge e ($\text{SEGMENT}(T.\text{pos_source}(e), T.\text{pos_target}(e))$).

LINE $T.\text{supporting_line}(\text{edge } e)$

returns the supporting line of edge e ($\text{LINE}(T.\text{pos_source}(e), T.\text{pos_target}(e))$).

int $T.\text{orientation}(\text{edge } e, \text{POINT } p)$

returns $\text{orientation}(T.\text{seg}(e), p)$.

int $T.\text{dim}()$

returns -1 if S is empty, returns 0 if S consists of only one point, returns 1 if S consists of at least two points and all points in S are collinear, and returns 2 otherwise.

list $\langle\text{POINT}\rangle$ $T.\text{points}()$

returns S .

bool $T.\text{get_bounding_box}(\text{POINT}\& \text{lower_left}, \text{POINT}\& \text{upper_right})$

returns the lower left and upper right corner of the bounding box of T . The operation returns *true*, if T is not empty, *false* otherwise.

list $\langle\text{node}\rangle$ $T.\text{get_convex_hull}()$

returns the convex hull of T .

edge $T.\text{get_hull_dart}()$

returns a dart of the outer face of T (i.e., a dart of the convex hull).

edge $T.\text{get_hull_edge}()$

as above.

bool $T.\text{is_hull_dart}(\text{edge } e)$

returns true if e is a dart of the convex hull of T , i.e., a dart on the face cycle of the outer face.

<i>bool</i>	$T.is_hullEdge(edge\ e)$	as above.
<i>bool</i>	$T.is_diagram_dart(edge\ e)$	returns true if e is a dart of the Delaunay diagram, i.e., either a dart on the convex hull or a dart where the incident triangles have distinct circumcircles.
<i>bool</i>	$T.is_diagram_edge(edge\ e)$	as above.
<i>edge</i>	$T.d_face_cycle_succ(edge\ e)$	returns the face cycle successor of e in the Delaunay diagram of T . <i>Precondition:</i> e belongs to the Delaunay diagram.
<i>edge</i>	$T.d_face_cycle_pred(edge\ e)$	returns the face cycle predecessor of e in the Delaunay diagram of T . <i>Precondition:</i> e belongs to the Delaunay diagram.
<i>bool</i>	$T.empty()$	decides whether T is empty.
<i>void</i>	$T.clear()$	makes T empty.
<i>edge</i>	$T.locate(POINT\ p, edge\ loc_start = NULL)$	returns an edge e of T that contains p or that borders the face that contains p . In the former case, a hull dart is returned if p lies on the boundary of the convex hull. In the latter case we have $T.orientation(e, p) > 0$ except if all points of T are collinear and p lies on the induced line. In this case $target(e)$ is visible from p . The function returns <i>nil</i> if T has no edge. The optional second argument is an edge of T , where the <i>locate</i> operation starts searching.
<i>edge</i>	$T.locate(POINT\ p, const\ list<edge>\&\ loc_start)$	returns $locate(p, e)$ with e in loc_start . If loc_start is empty, we return $locate(p, NULL)$. The operation tries to choose a good starting edge for the <i>locate</i> operation from loc_start . <i>Precondition:</i> All edges in loc_start must be edges of T .
<i>node</i>	$T.lookup(POINT\ p, edge\ loc_start = NULL)$	if T contains a node v with $pos(v) = p$ the result is v otherwise the result is <i>nil</i> . The optional second argument is an edge of T , where the <i>locate</i> operation starts searching p .

<i>node</i>	<i>T.lookup</i> (<i>POINT p</i> , <i>const list<edge>& loc_start</i>)	returns <i>lookup(p, e)</i> with <i>e</i> in <i>loc_start</i> . If <i>loc_start</i> is empty, we return <i>lookup(p, NULL)</i> . The operation tries to choose a good starting edge for the <i>lookup</i> operation from <i>loc_start</i> . <i>Precondition:</i> All edges in <i>loc_start</i> must be edges of <i>T</i> .
<i>node</i>	<i>T.insert</i> (<i>POINT p</i>)	inserts point <i>p</i> into <i>T</i> and returns the corresponding node. More precisely, if there is already a node <i>v</i> in <i>T</i> positioned at <i>p</i> (i.e., <i>pos(v)</i> is equal to <i>p</i>) then <i>pos(v)</i> is changed to <i>p</i> (i.e., <i>pos(v)</i> is made identical to <i>p</i>) and if there is no such node then a new node <i>v</i> with <i>pos(v) = p</i> is added to <i>T</i> . In either case, <i>v</i> is returned.
<i>void</i>	<i>T.del</i> (<i>node v</i>)	removes the node <i>v</i> , i.e., makes <i>T</i> a Delaunay triangulation for $S \setminus \{pos(v)\}$.
<i>void</i>	<i>T.del</i> (<i>POINT p</i>)	removes the node <i>p</i> , i.e., makes <i>T</i> a Delaunay triangulation for $S \setminus p$.
<i>node</i>	<i>T.nearest_neighbor</i> (<i>POINT p</i>)	computes a node <i>v</i> of <i>T</i> that is closest to <i>p</i> , i.e., $dist(p, pos(v)) = \min\{ dist(p, pos(u)) \mid u \in T \}$. This is a non-const operation.
<i>node</i>	<i>T.nearest_neighbor</i> (<i>node w</i>)	computes a node <i>v</i> of <i>T</i> that is closest to $p = T[w]$, i.e., $dist(p, pos(v)) = \min\{ dist(p, pos(u)) \mid u \in T \}$.
<i>list<node></i>	<i>T.nearest_neighbors</i> (<i>POINT p</i> , <i>int k</i>)	returns the <i>k</i> nearest neighbors of <i>p</i> , i.e., a list of the $\min(k, S)$ nodes of <i>T</i> closest to <i>p</i> . The list is ordered by distance from <i>p</i> . This is a non-const operation.
<i>list<node></i>	<i>T.nearest_neighbors</i> (<i>node w</i> , <i>int k</i>)	returns the <i>k</i> nearest neighbors of $p = T[w]$, i.e., a list of the $\min(k, S)$ nodes of <i>T</i> closest to <i>p</i> . The list is ordered by distance from <i>p</i> .
<i>list<node></i>	<i>T.range_search</i> (<i>const CIRCLE& C</i>)	returns the list of all nodes contained in the closure of disk <i>C</i> . <i>Precondition:</i> <i>C</i> must be a proper circle (not a straight line). This is a non-const operation.

- list<node>* `T.range_search(node v, const POINT& p)`
 returns the list of all nodes contained in the closure of disk C with center $pos[v]$ and having p in its boundary.
- list<node>* `T.range_search(const POINT& a, const POINT& b, const POINT& c)`
 returns the list of all nodes contained in the closure of the triangle (a, b, c) .
Precondition: $a, b,$ and c must not be collinear.
 This is a non-const operation.
- list<node>* `T.range_search_parallelogram(const POINT& a, const POINT& b, const POINT& c)`
 returns the list of all nodes contained in the closure of the parallelogram (a, b, c, d) with $d = a + (c - b)$.
Precondition: $a, b,$ and c must not be collinear.
 This is a non-const operation.
- list<node>* `T.range_search(const POINT& a, const POINT& b)`
 returns the list of all nodes contained in the closure of the rectangle with diagonal (a, b) . This is a non-const operation.
- list<edge>* `T.minimum_spanning_tree()`
 returns the list of edges of T that comprise a minimum spanning tree of S .
- list<edge>* `T.relative_neighborhood_graph()`
 returns the list of edges of T that comprise a relative neighborhood graph of S .
- void* `T.compute_voronoi(GRAPH<CIRCLE, POINT>& V)`
 computes the corresponding Voronoi diagram V . Each node of VD is labeled with its defining circle. Each edge is labeled with the site lying in the face to its left.

Drawing Routines

The functions in this section were designed to support the drawing of Delaunay triangulations and Voronoi diagrams.

- void* `T.draw_nodes(void (*draw_node)(const POINT&))`
 calls `draw_node(pos(v))` for every node v of T .

void T.draw_edge(*edge e*, *void (*draw_diagram_edge)(const POINT& , const POINT&)*,
*void (*draw_triang_edge) (const POINT& , const POINT&)*,
*void (*draw_hull_dart) (const POINT& , const POINT&)*)
 calls *draw_diagram_edge(pos_source(e), pos_target(e))* if *e* is a diagram
 dart, *draw_hull_dart(pos_source(e), pos_target(e))* if *e* is a hull dart, and
draw_triang_edge(pos_source(e), pos_target(e)) if *e* is a non-diagram edge.

void T.draw_edges(*void (*draw_diagram_edge)(const POINT& , const POINT&)*,
*void (*draw_triang_edge) (const POINT& , const POINT&)*,
*void (*draw_hull_dart) (const POINT& , const POINT&)*)
 calls the corresponding function for all edges of *T*.

void T.draw_edges(*const list<edge>& L*, *void (*draw_edge)(const POINT& ,*
const POINT&))
 calls *draw_edge(pos_source(e), pos_target(e))* for every edge $e \in L$.

void T.draw_voro_edges(*void (*draw_edge)(const POINT& , const POINT&)*,
*void (*draw_ray) (const POINT& , const POINT&)*)
 calls *draw_edge* and *draw_ray* for the edges of the Voronoi diagram.

void T.draw_hull(*void (*draw_poly)(const list<POINT>&)*)
 calls *draw_poly* with the list of vertices of the convex hull.

void T.draw_voro(*const GRAPH<CIRCLE, POINT>& ,*
*void (*draw_node)(const POINT&)*,
*void (*draw_edge)(const POINT& , const POINT&)*,
*void (*draw_ray) (const POINT& , const POINT&)*)
 calls ...

4. Implementation

The main ingredients for the implementation are Delaunay flipping, segment walking, and plane sweep.

The constructor *POINT_SET(list<POINT> S)* first constructs a triangulation of *S* by sweeping and then makes the triangulation Delaunay by a sequence of Delaunay flips.

Locate walks through the triangulation along the segment from some fixed point of *T* to the query point. *Insert* first locates the point, then updates the triangulation locally, and finally performs flips to reestablish the Delaunay property. *Delete* deletes the node, retriangulates the resulting face, and then performs flips. Nearest neighbor searching, circular range queries, and triangular range queries insert the query point into the triangulation, then perform an appropriate graph search on the triangulation, and finally remove the query point.

All algorithms show good expected behavior.

For details we refer the reader to the LEDA implementation report "Point Sets and Dynamic Delaunay Triangulations".

16.3 Point Location in Triangulations (POINT_LOCATOR)

1. Definition

An instance PS of data type $POINT_LOCATOR$ is a data structure for efficient point location in triangulations.

There are three instantiations of $POINT_LOCATOR$: $point_locator$ (floating point kernel), $rat_point_locator$ (rational kernel) and $real_point_locator$ (real kernel). The respective header file name corresponds to the type name (with “.h” appended).

```
#include < LEDA/geo/generic/POINT_LOCATOR.h >
```

2. Creation

```
POINT_LOCATOR PS(const GRAPH<POINT, int>& T);
```

creates a point locator for a triangulation T .

```
POINT_LOCATOR PS(const GRAPH<POINT, SEGMENT>& T);
```

creates a point locator for a constrained triangulation T .

```
POINT_LOCATOR PS(const graph& T, node_array<POINT>& p);
```

creates a point locator for a general triangulation T . Node positions have to be provided in node_array p .

3. Operations

```
edge PS.locate(POINT q)
```

returns an edge e of PS that contains q or that borders the face that contains q . In the former case, a hull edge is returned if q lies on the boundary of the convex hull. In the latter case we have $PS.orientation(e, q) > 0$ except if all points of PS are collinear and q lies on the induced line. In this case $target(e)$ is visible from q . The operation returns nil if PS is empty.

```
bool PS.check_locate(POINT q, edge e)
```

checks whether e could be the result of $PS.locate(q)$.

16.4 Sets of Intervals (interval_set)

1. Definition

An instance S of the parameterized data type $interval_set\langle I \rangle$ is a collection of items (is_item). Every item in S contains a closed interval of the *double* numbers as key and an information from data type I , called the information type of S . The number of items in S is called the size of S . An interval set of size zero is said to be empty. We use $\langle x, y, i \rangle$ to denote the item with interval $[x, y]$ and information i ; x (y) is called the left (right) boundary of the item. For each interval $[x, y]$ there is at most one item $\langle x, y, i \rangle \in S$.

```
#include < LEDA/geo/interval_set.h >
```

2. Creation

$interval_set\langle I \rangle S$; creates an instance S of type $interval_set\langle I \rangle$ and initializes S to the empty set.

3. Operations

<i>double</i>	$S.left(is_item\ it)$	returns the left boundary of item it . <i>Precondition:</i> it is an item in S .
<i>double</i>	$S.right(is_item\ it)$	returns the right boundary of item it . <i>Precondition:</i> it is an item in S .
<i>const I&</i>	$S.inf(is_item\ it)$	returns the information of item it . <i>Precondition:</i> it is an item in S .
<i>is_item</i>	$S.insert(double\ x,\ double\ y,\ const\ I\&\ i)$	associates the information i with interval $[x, y]$. If there is an item $\langle x, y, j \rangle$ in S then j is replaced by i , else a new item $\langle x, y, i \rangle$ is added to S . In both cases the item is returned.
<i>is_item</i>	$S.lookup(double\ x,\ double\ y)$	returns the item with interval $[x, y]$ (nil if no such item exists in S).
$list\langle is_item \rangle$	$const\ S.intersection(double\ a,\ double\ b)$	returns all items $\langle x, y, i \rangle \in S$ with $[x, y] \cap [a, b] \neq \emptyset$.
<i>void</i>	$S.del(double\ x,\ double\ y)$	deletes the item with interval $[x, y]$ from S .
<i>void</i>	$S.delItem(is_item\ it)$	removes item it from S . <i>Precondition:</i> it is an item in S .

<i>void</i>	<i>S.change_inf(is_item it, const I& i)</i>	makes <i>i</i> the information of item <i>it</i> . <i>Precondition: it</i> is an item in <i>S</i> .
<i>void</i>	<i>S.clear()</i>	makes <i>S</i> the empty <code>interval_set</code> .
<i>bool</i>	<i>S.empty()</i>	returns true iff <i>S</i> is empty.
<i>int</i>	<i>S.size()</i>	returns the size of <i>S</i> .

4. Implementation

Interval sets are implemented by two-dimensional range trees [90, 57]. Operations `insert`, `lookup`, `del_item` and `del` take time $O(\log^2 n)$, `intersection` takes time $O(k + \log^2 n)$, where k is the size of the returned list. Operations `left`, `right`, `inf`, `empty`, and `size` take time $O(1)$, and `clear` $O(n \log n)$. Here n is always the current size of the interval set. The space requirement is $O(n \log n)$.

16.5 Sets of Parallel Segments (`segment_set`)

1. Definition

An instance S of the parameterized data type `segment_set<I>` is a collection of items (`seg_item`). Every item in S contains as key a line segment with a fixed direction α (see data type `segment`) and an information from data type I , called the information type of S . α is called the orientation of S . We use $\langle s, i \rangle$ to denote the item with segment s and information i . For each segment s there is at most one item $\langle s, i \rangle \in S$.

```
#include < LEDA/geo/segment_set.h >
```

2. Creation

```
segment_set<I> S; creates an empty instance  $S$  of type segment_set<I> with orientation zero, i.e., horizontal segments.
```

```
segment_set<I> S(int rot);  
creates an empty instance  $S$  of type segment_set<I> with orientation  $rot \cdot \pi/2$ .
```

```
segment_set<I> S(double a);  
creates an empty instance  $S$  of type segment_set<I> with orientation  $a$ . (Note that there may be incorrect results due to rounding errors.)
```

3. Operations

```
segment      S.key(seg_item it)      returns the segment of item  $it$ .  
Precondition:  $it$  is an item in  $S$ .
```

```
const I&      S.inf(seg_item it)      returns the information of item  $it$ .  
Precondition:  $it$  is an item in  $S$ .
```

```
seg_item      S.insert(const segment& s, const I& i)  
associates the information  $i$  with segment  $s$ . If there is an item  $\langle s, j \rangle$  in  $S$  then  $j$  is replaced by  $i$ , else a new item  $\langle s, i \rangle$  is added to  $S$ . In both cases the item is returned.
```

```
seg_item      S.lookup(const segment& s)  
returns the item with segment  $s$  (nil if no such item exists in  $S$ ).
```

```
list<seg_item> S.intersection(const segment& q)  
returns all items  $\langle s, i \rangle \in S$  with  $s \cap q \neq \emptyset$ .  
Precondition:  $q$  is orthogonal to the segments in  $S$ .
```

- list<seg_item>* *S.intersection_sorted(const segment& q)*
as above, but the returned segments are ordered as they are intersected by *q* if one travels from *q.source()* to *q.target()*.
- list<seg_item>* *S.intersection(const line& l)*
returns all items $\langle s, i \rangle \in S$ with $s \cap l \neq \emptyset$.
Precondition: *l* is orthogonal to the segments in *S*.
- list<seg_item>* *S.intersection_sorted(const line& l)*
as above, but the returned segments are ordered as they are intersected by *l* if one travels along *l* in direction *l.direction()*.
- void* *S.del(const segment& s)* deletes the item with segment *s* from *S*.
- void* *S.delItem(seg_item it)* removes item *it* from *S*.
Precondition: *it* is an item in *S*.
- void* *S.change_inf(seg_item it, const I& i)*
makes *i* the information of item *it*.
Precondition: *it* is an item in *S*.
- void* *S.clear()* makes *S* the empty *segment_set*.
- bool* *S.empty()* returns true iff *S* is empty.
- int* *S.size()* returns the size of *S*.

4. Implementation

Segment sets are implemented by dynamic segment trees based on BB[α] trees ([90, 57]) trees. Operations *key*, *inf*, *change_inf*, *empty*, and *size* take time $O(1)$, *insert*, *lookup*, *del*, and *delItem* take time $O(\log^2 n)$ and an intersection operation takes time $O(k + \log^2 n)$, where *k* is the size of the returned list. Here *n* is the current size of the set. The space requirement is $O(n \log n)$.

16.6 Sets of Parallel Rational Segments (*rat_segment_set*)

1. Definition

An instance S of the parameterized data type *rat_segment_set* $\langle I \rangle$ is a collection of items (*seg_item*). Every item in S contains as key a rational line segment with a fixed direction α (see data type *rat_segment*) and an information from data type I , called the information type of S . α is called the orientation of S , it must be a multiple of $\pi/2$. We use $\langle s, i \rangle$ to denote the item with segment s and information i . For each segment s there is at most one item $\langle s, i \rangle \in S$.

```
#include < LEDA/geo/rat_segment_set.h >
```

2. Creation

```
rat_segment_set $\langle I \rangle$   $S$ ;
```

creates an empty instance S of type *rat_segment_set* $\langle I \rangle$ with orientation zero, i.e., horizontal segments.

```
rat_segment_set $\langle I \rangle$   $S$ (int  $rot$ );
```

creates an empty instance S of type *rat_segment_set* $\langle I \rangle$ with orientation $rot \cdot \pi/2$.

3. Operations

```
rat_segment  $S$ .key(seg_item  $it$ )
```

returns the segment of item it .
Precondition: it is an item in S .

```
const I &  $S$ .inf(seg_item  $it$ )
```

returns the information of item it .
Precondition: it is an item in S .

```
seg_item  $S$ .insert(const rat_segment &  $s$ , const I &  $i$ )
```

associates the information i with segment s . If there is an item $\langle s, j \rangle$ in S then j is replaced by i , else a new item $\langle s, i \rangle$ is added to S . In both cases the item is returned.

```
seg_item  $S$ .lookup(const rat_segment &  $s$ )
```

returns the item with segment s (nil if no such item exists in S).

```
list $\langle$ seg_item $\rangle$   $S$ .intersection(const rat_segment &  $q$ )
```

returns all items $\langle s, i \rangle \in S$ with $s \cap q \neq \emptyset$.
Precondition: q is orthogonal to the segments in S .

list<seg_item> *S.intersection_sorted(const rat_segment& q)*

as above, but the returned segments are ordered as they are intersected by *q* if one travels from *q.source()* to *q.target()*.

list<seg_item> *S.intersection(const rat_line& l)*

returns all items $\langle s, i \rangle \in S$ with $s \cap l \neq \emptyset$.
Precondition: *l* is orthogonal to the segments in *S*.

list<seg_item> *S.intersection_sorted(const rat_line& l)*

as above, but the returned segments are ordered as they are intersected by *l* if one travels along *l* in direction *l.direction()*.

void *S.del(const rat_segment& s)*

deletes the item with segment *s* from *S*.

void *S.delItem(seg_item it)* removes item *it* from *S*.

Precondition: *it* is an item in *S*.

void *S.change_inf(seg_item it, const I& i)*

makes *i* the information of item *it*.
Precondition: *it* is an item in *S*.

void *S.clear()*

makes *S* the empty *rat_segment_set*.

bool *S.empty()*

returns true iff *S* is empty.

int *S.size()*

returns the size of *S*.

4. Implementation

Segment sets are implemented by dynamic segment trees based on BB[α] trees ([90, 57]) trees. Operations *key*, *inf*, *change_inf*, *empty*, and *size* take time $O(1)$, *insert*, *lookup*, *del*, and *del_item* take time $O(\log^2 n)$ and an intersection operation takes time $O(k + \log^2 n)$, where *k* is the size of the returned list. Here *n* is the current size of the set. The space requirement is $O(n \log n)$.

16.7 Planar Subdivisions (subdivision)

1. Definition

An instance S of the parameterized data type *subdivision*< I > is a subdivision of the two-dimensional plane, i.e., an embedded planar graph with straight line edges (see also sections 12.6 and 12.7). With each node v of S is associated a point, called the position of v and with each face of S is associated an information from data type I , called the information type of S .

```
#include < LEDA/geo/subdivision.h >
```

2. Creation

```
subdivision< $I$ >  $S$ (GRAPH<point,  $I$ >&  $G$ );
```

creates an instance S of type *subdivision*< I > and initializes it to the subdivision represented by the parameterized directed graph G . The node entries of G (of type *point*) define the positions of the corresponding nodes of S . Every face f of S is assigned the information of one of its bounding edges in G .

Precondition: G represents a planar subdivision, i.e., a straight line embedded planar map.

3. Operations

<i>point</i>	S .position(<i>node</i> v)	returns the position of node v .
<i>const I</i> &	S .inf(<i>face</i> f)	returns the information of face f .
<i>face</i>	S .locate_point(<i>point</i> p)	returns the face containing point p .
<i>face</i>	S .outer_face()	returns the outer face of S .

4. Implementation

Planar subdivisions are implemented by parameterized planar maps and an additional data structure for point location based on partially persistent search trees[25]. Operations position and inf take constant time, a locate_point operation takes (expected) time $O(\log n)$. Here n is the number of nodes. The space requirement is $O(n + m)$ and the initialization time is $O(n + m \log m)$, where m is the number of edges in the map.

Chapter 17

Basic Data Types for Three-Dimensional Geometry

17.1 Points in 3D-Space (`d3_point`)

1. Definition

An instance of the data type `d3_point` is a point in the three-dimensional space \mathbb{R}^3 . We use (x, y, z) to denote a point with first (or x-) coordinate x , second (or y-) coordinate y , and third (or z-) coordinate z .

```
#include < LEDA/geo/d3_point.h >
```

2. Creation

`d3_point p;` introduces a variable p of type `d3_point` initialized to the point $(0, 0, 0)$.

`d3_point p(double x, double y, double z);`
introduces a variable p of type `d3_point` initialized to the point (x, y, z) .

`d3_point p(vector v);`
introduces a variable p of type `d3_point` initialized to the point $(v[0], v[1], v[2])$.
Precondition: $v.dim() = 3$.

3. Operations

`double p.xcoord()` returns the first coordinate of p .

`double p.ycoord()` returns the second coordinate of p .

`double p.zcoord()` returns the third coordinate of p .

`vector p.to_vector()` returns the vector $x\vec{y}z$.

`point p.project_xy()` returns p projected into the xy-plane.

`point p.project_yz()` returns p projected into the yz-plane.

`point p.project_xz()` returns p projected into the xz-plane.

`double p.sqr_dist(const d3_point& q)`
returns the square of the Euclidean distance between p and q .

`double p.xdist(const d3_point& q)`
returns the x-distance between p and q .

- double* *p.ydist(const d3_point& q)*
 returns the y-distance between *p* and *q*.
- double* *p.zdist(const d3_point& q)*
 returns the z-distance between *p* and *q*.
- double* *p.distance(const d3_point& q)*
 returns the Euclidean distance between *p* and *q*.
- double* *p.distance()* returns the Euclidean distance between *p* and the origin.
- d3_point* *p.translate(double dx, double dy, double dz)*
 returns *p* translated by vector (dx, dy, dz) .
- d3_point* *p.translate(const vector& v)*
 returns $p+v$, i.e., *p* translated by vector *v*.
 Precondition: v.dim() = 3.
- d3_point* *p + const vector& v* returns *p* translated by vector *v*.
- d3_point* *p - const vector& v* returns *p* translated by vector $-v$.
- d3_point* *p.reflect(const d3_point& q, const d3_point& r, const d3_point& s)*
 returns *p* reflected across the plane passing through *q*, *r*
 and *s*.
- d3_point* *p.reflect(const d3_point& q)*
 returns *p* reflected across point *q*.
- d3_point* *p.rotate_around_axis(int a, double phi)*
 returns *p* rotated by angle *phi* around the *x*-axis if $a = 1$,
 around the *y*-axis if $a = 1$, or around the *z*-axis if $a = 2$.
- d3_point* *p.rotate_around_vector(const vector& u, double phi)*
 returns *p* rotated by angle *phi* around the axis defined
 by vector *u*.
- d3_point* *p.cartesian_to_polar()* returns *p* converted to polar coordinates.
- d3_point* *p.polar_to_cartesian()* returns *p* converted to cartesian coordinates.
- vector* *p - const d3_point& q*
 returns the difference vector of the coordinates.
- ostream&* *ostream& O << const d3_point& p*
 writes *p* to output stream *O*.

istream& *istream& I* \gg *d3_point& p*

reads the coordinates of p (three *double* numbers) from input stream I .

Non-Member Functions

int `cmp_distances(const d3_point& p1, const d3_point& p2, const d3_point& p3, const d3_point& p4)`

compares the distances $(p1, p2)$ and $(p3, p4)$. Returns +1 (−1) if distance $(p1, p2)$ is larger (smaller) than distance $(p3, p4)$, otherwise 0.

d3_point `center(const d3_point& a, const d3_point& b)`

returns the center of a and b , i.e. $a + \vec{ab}/2$.

d3_point `midpoint(const d3_point& a, const d3_point& b)`

returns the center of a and b .

int `orientation(const d3_point& a, const d3_point& b, const d3_point& c, const d3_point& d)`

computes the orientation of points a, b, c , and d as the sign of the determinant

$$\begin{vmatrix} 1 & 1 & 1 & 1 \\ a_x & b_x & c_x & d_x \\ a_y & b_y & c_y & d_y \\ a_z & b_z & c_z & d_z \end{vmatrix}$$

int `orientation_xy(const d3_point& a, const d3_point& b, const d3_point& c)`

returns the orientation of the projections of a, b and c into the xy -plane.

int `orientation_yz(const d3_point& a, const d3_point& b, const d3_point& c)`

returns the orientation of the projections of a, b and c into the yz -plane.

int `orientation_xz(const d3_point& a, const d3_point& b, const d3_point& c)`

returns the orientation of the projections of a, b and c into the xz -plane.

double `volume(const d3_point& a, const d3_point& b, const d3_point& c, const d3_point& d)`

computes the signed volume of the simplex determined by a, b, c , and d , positive if $orientation(a, b, c, d) > 0$ and negative otherwise.

- bool* `collinear(const d3_point& a, const d3_point& b, const d3_point& c)`
returns true if points a, b, c are collinear and false otherwise.
- bool* `coplanar(const d3_point& a, const d3_point& b, const d3_point& c,
const d3_point& d)`
returns true if points a, b, c, d are coplanar and false otherwise.
- int* `side_of_sphere(const d3_point& a, const d3_point& b, const d3_point& c,
const d3_point& d, const d3_point& x)`
returns +1 (-1) if point x lies on the positive (negative) side of the oriented sphere through points a, b, c , and d , and 0 if x is contained in this sphere.
- int* `region_of_sphere(const d3_point& a, const d3_point& b, const d3_point& c,
const d3_point& d, const d3_point& x)`
determines whether the point x lies inside (= +1), on (= 0), or outside (= -1) the sphere through points a, b, c, d , (equivalent to $orientation(a, b, c, d) * side_of_sphere(a, b, c, d, x)$)
Precondition: $orientation(A) \neq 0$
- bool* `contained_in_simplex(const d3_point& a, const d3_point& b,
const d3_point& c, const d3_point& d,
const d3_point& x)`
determines whether x is contained in the simplex spanned by the points a, b, c, d .
Precondition: a, b, c, d are affinely independent.
- bool* `contained_in_simplex(const array<d3_point>& A, const d3_point& x)`
determines whether x is contained in the simplex spanned by the points in A .
Precondition: A must have size ≤ 4 and the points in A must be affinely independent.
- bool* `contained_in_affine_hull(const list<d3_point>& L, const d3_point& x)`
determines whether x is contained in the affine hull of the points in L .
- bool* `contained_in_affine_hull(const array<d3_point>& A, const d3_point& x)`
determines whether x is contained in the affine hull of the points in A .
- int* `affine_rank(const array<d3_point>& L)`
computes the affine rank of the points in L .
- int* `affine_rank(const array<d3_point>& A)`
computes the affine rank of the points in A .

- bool* `affinely_independent(const list<d3_point>& L)`
 decides whether the points in A are affinely independent.
- bool* `affinely_independent(const array<d3_point>& A)`
 decides whether the points in A are affinely independent.
- bool* `inside_sphere(const d3_point& a, const d3_point& b, const d3_point& c,`
 `const d3_point& d, const d3_point& e)`
 returns *true* if point e lies in the interior of the sphere
 through points a , b , c , and d , and *false* otherwise.
- bool* `outside_sphere(const d3_point& a, const d3_point& b, const d3_point& c,`
 `const d3_point& d, const d3_point& e)`
 returns *true* if point e lies in the exterior of the sphere
 through points a , b , c , and d , and *false* otherwise.
- bool* `on_sphere(const d3_point& a, const d3_point& b, const d3_point& c,`
 `const d3_point& d, const d3_point& e)`
 returns *true* if a , b , c , d , and e lie on a common sphere.
- d3_point* `point_on_positive_side(const d3_point& a, const d3_point& b,`
 `const d3_point& c)`
 returns a point d with $orientation(a, b, c, d) > 0$.

17.2 Straight Rays in 3D-Space (d3_ray)

1. Definition

An instance r of the data type $d3_ray$ is a directed straight ray in three-dimensional space.

```
#include < LEDA/geo/d3_ray.h >
```

2. Creation

```
d3_ray r(const d3_point& p1, const d3_point& p2);
```

introduces a variable r of type $d3_ray$. r is initialized to the ray starting at point $p1$ and going through $p2$.

```
d3_ray r(const d3_segment& s);
```

introduces a variable r of type $d3_ray$. r is initialized to $ray(s.source(), s.target())$.

3. Operations

```
d3_point r.source() returns the source of r.
```

```
d3_point r.point1() returns the source of r.
```

```
d3_point r.point2() returns a point on r different from the source.
```

```
d3_segment r.seg() returns a segment on r.
```

```
bool r.contains(const d3_point& p)
returns true if p lies on r.
```

```
bool r.contains(const d3_segment& s)
returns true if s lies on r.
```

```
bool r.intersection(const d3_segment& s, d3_point& inter)
if s and r intersect in a single point, true is returned
and the point of intersection is assigned to inter. Other-
wise false is returned.
```

```
bool r.intersection(const d3_ray& r, d3_point& inter)
if r and r intersect in a single point, true is returned
and the point of intersection is assigned to inter. Other-
wise false is returned.
```

```
bool r.project_xy(ray& m) if the projection of r into the xy plane is not a point,
the function returns true and assigns the projection
to m. Otherwise false is returned.
```

<i>bool</i>	<i>r.project_xz(ray& m)</i>	if the projection of <i>r</i> into the <i>xz</i> plane is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>bool</i>	<i>r.project_yz(ray& m)</i>	if the projection of <i>r</i> into the <i>yz</i> plane is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>bool</i>	<i>r.project(const d3_point& p, const d3_point& q, const d3_point& v, d3_ray& m)</i>	if the projection of <i>r</i> into the plane through (p, q, v) is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>d3_ray</i>	<i>r.reverse()</i>	returns a ray starting at <i>r.source()</i> with direction - <i>r.to_vector()</i> .
<i>d3_ray</i>	<i>r.translate(const vector& v)</i>	returns <i>r</i> translated by vector <i>v</i> . Precond. : <i>v.dim()</i> = 3 .
<i>d3_ray</i>	<i>r.translate(double dx, double dy, double dz)</i>	returns <i>r</i> translated by vector (dx, dy, dz) .
<i>d3_ray</i>	<i>r + const vector& v</i>	returns <i>r</i> translated by vector <i>v</i> .
<i>d3_ray</i>	<i>r - const vector& v</i>	returns <i>r</i> translated by vector $-v$.
<i>d3_ray</i>	<i>r.reflect(const d3_point& p, const d3_point& q, const d3_point& v)</i>	returns <i>r</i> reflected across the plane through (p, q, v) .
<i>d3_ray</i>	<i>r.reflect(const d3_point& p)</i>	returns <i>r</i> reflected across <i>p</i> .
<i>vector</i>	<i>r.to_vector()</i>	returns <i>point2()</i> - <i>point1()</i> .

17.3 Segments in 3D-Space (d3_segment)

1. Definition

An instance s of the data type $d3_segment$ is a directed straight line segment in three-dimensional space, i.e., a straight line segment $[p, q]$ connecting two points $p, q \in \mathbb{R}^3$. p is called the *source* or start point and q is called the *target* or end point of s . The length of s is the Euclidean distance between p and q . A segment is called *trivial* if its source is equal to its target. If s is not trivial, we use $line(s)$ to denote the straight line containing s .

```
#include < LEDA/geo/d3_segment.h >
```

2. Creation

```
d3_segment s(const d3_point& p1, const d3_point& p2);
```

introduces a variable s of type $d3_segment$. s is initialized to the segment from $p1$ to $p2$.

```
d3_segment s;
```

introduces a variable s of type $d3_segment$. s is initialized to the segment from $(0, 0, 0)$ to $(1, 0, 0)$.

3. Operations

```
bool s.contains(const d3_point& p)
```

decides whether s contains p .

```
d3_point s.source()
```

returns the source point of segment s .

```
d3_point s.target()
```

returns the target point of segment s .

```
double s.xcoord1()
```

returns the x-coordinate of $s.source()$.

```
double s.xcoord2()
```

returns the x-coordinate of $s.target()$.

```
double s.ycoord1()
```

returns the y-coordinate of $s.source()$.

```
double s.ycoord2()
```

returns the y-coordinate of $s.target()$.

```
double s.zcoord1()
```

returns the z-coordinate of $s.source()$.

```
double s.zcoord2()
```

returns the z-coordinate of $s.target()$.

```
double s.dx()
```

returns $xcoord2() - xcoord1()$.

```
double s.dy()
```

returns $ycoord2() - ycoord1()$.

```
double s.dz()
```

returns $zcoord2() - zcoord1()$.

<i>segment</i>	<code>s.project_xy()</code>	returns the projection into the xy plane.
<i>segment</i>	<code>s.project_xz()</code>	returns the projection into the xz plane.
<i>segment</i>	<code>s.project_yz()</code>	returns the projection into the yz plane.
<i>d3_segment</i>	<code>s.project(const d3_point& p, const d3_point& q, const d3_point& v)</code>	returns <i>s</i> projected into the plane through (p, q, v) .
<i>d3_segment</i>	<code>s.reflect(const d3_point& p, const d3_point& q, const d3_point& v)</code>	returns <i>s</i> reflected across the plane through (p, q, v) .
<i>d3_segment</i>	<code>s.reflect(const d3_point& p)</code>	returns <i>s</i> reflected across point <i>p</i> .
<i>d3_segment</i>	<code>s.reverse()</code>	returns <i>s</i> reversed.
<i>vector</i>	<code>s.to_vector()</code>	returns $s.target() - s.source()$.
<i>bool</i>	<code>s.intersection(const d3_segment& t)</code>	decides, whether <i>s</i> and <i>t</i> intersect in a single point.
<i>bool</i>	<code>s.intersection(const d3_segment& t, d3_point& p)</code>	decides, whether <i>s</i> and <i>t</i> intersect in a single point. If they intersect in a single point, the point is assigned to <i>p</i> and the result is true, otherwise the result is false
<i>bool</i>	<code>s.intersection_of_lines(const d3_segment& t, d3_point& p)</code>	If $line(s)$ and $line(t)$ intersect in a single point this point is assigned to <i>p</i> and the result is true, otherwise the result is false.
<i>bool</i>	<code>s.is_trivial()</code>	returns true if <i>s</i> is trivial.
<i>double</i>	<code>s.sqr_length()</code>	returns the square of the length of <i>s</i> .
<i>double</i>	<code>s.length()</code>	returns the length of <i>s</i> .
<i>d3_segment</i>	<code>s.translate(const vector& v)</code>	returns <i>s</i> translated by vector <i>v</i> . <i>Precond.</i> : $v.dim() = 3$.
<i>d3_segment</i>	<code>s.translate(double dx, double dy, double dz)</code>	returns <i>s</i> translated by vector (dx, dy, dz) .
<i>d3_segment</i>	<code>s + const vector& v</code>	returns <i>s</i> translated by vector <i>v</i> .
<i>d3_segment</i>	<code>s - const vector& v</code>	returns <i>s</i> translated by vector $-v$.

17.4 Straight Lines in 3D-Space (d3_line)

1. Definition

An instance l of the data type $d3_line$ is a directed straight line in three-dimensional space.

```
#include < LEDA/geo/d3_line.h >
```

2. Creation

```
 $d3\_line$   $l$ (const  $d3\_point\&$   $p1$ , const  $d3\_point\&$   $p2$ );
```

introduces a variable l of type $d3_line$. l is initialized to the line through points $p1, p2$.

Precondition : $p1 \neq p2$.

```
 $d3\_line$   $l$ (const  $d3\_segment\&$   $s$ );
```

introduces a variable l of type $d3_line$. l is initialized to the line supporting segment s .

Precondition : s is not trivial.

```
 $d3\_line$   $l$ ;
```

introduces a variable l of type $d3_line$. l is initialized to the line through points $(0, 0, 0)$ and $(1, 0, 0)$.

3. Operations

```
 $bool$   $l$ .contains(const  $d3\_point\&$   $p$ )
```

returns true if p lies on l .

```
 $d3\_point$   $l$ .point1()
```

returns a point on l .

```
 $d3\_point$   $l$ .point2()
```

returns a second point on l .

```
 $d3\_segment$   $l$ .seg()
```

returns a non-trivial segment on l with the same direction.

```
 $bool$   $l$ .project_xy( $line\&$   $m$ )
```

if the projection of l into the xy plane is not a point, the function returns true and assigns the projection to m . Otherwise false is returned.

```
 $bool$   $l$ .project_xz( $line\&$   $m$ )
```

if the projection of l into the xz plane is not a point, the function returns true and assigns the projection to m . Otherwise false is returned.

```
 $bool$   $l$ .project_yz( $line\&$   $m$ )
```

if the projection of l into the yz plane is not a point, the function returns true and assigns the projection to m . Otherwise false is returned.

<i>bool</i>	<i>l.project(const d3_point& p, const d3_point& q, const d3_point& v, d3_line& m)</i>	if the projection of <i>l</i> into the plane through (p, q, v) is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>d3_line</i>	<i>l.translate(double dx, double dy, double dz)</i>	returns <i>l</i> translated by vector (dx, dy, dz) .
<i>d3_line</i>	<i>l.translate(const vector& v)</i>	returns <i>l</i> translated by <i>v</i> . Precond. : $v.dim() = 3$.
<i>d3_line</i>	<i>l + const vector& v</i>	returns <i>l</i> translated by vector <i>v</i> .
<i>d3_line</i>	<i>l - const vector& v</i>	returns <i>l</i> translated by vector $-v$.
<i>d3_line</i>	<i>l.reflect(const d3_point& p, const d3_point& q, const d3_point& v)</i>	returns <i>l</i> reflected across the plane through (p, q, v) .
<i>d3_line</i>	<i>l.reflect(const d3_point& p)</i>	returns <i>l</i> reflected across point <i>p</i> .
<i>d3_line</i>	<i>l.reverse()</i>	returns <i>l</i> reversed.
<i>vector</i>	<i>l.to_vector()</i>	returns $point2() - point1()$.
<i>bool</i>	<i>l.intersection(const d3_segment& s)</i>	decides, whether <i>l</i> and <i>s</i> intersect in a single point.
<i>bool</i>	<i>l.intersection(const d3_segment& s, d3_point& p)</i>	decides, whether <i>l</i> and <i>s</i> intersect in a single point. If so, the point of intersection is assigned to <i>p</i> .
<i>bool</i>	<i>l.intersection(const d3_line& m)</i>	decides, whether <i>l</i> and <i>m</i> intersect.
<i>bool</i>	<i>l.intersection(const d3_line& m, d3_point& p)</i>	decides, whether <i>l</i> and <i>m</i> intersect in a single point. If so, the point of intersection is assigned to <i>p</i> .
<i>double</i>	<i>l.sqr_dist(const d3_point& p)</i>	returns the square of the distance between <i>l</i> and <i>p</i> .
<i>double</i>	<i>l.distance(const d3_point& p)</i>	returns the distance between <i>l</i> and <i>p</i> .

17.5 Planes (d3_plane)

1. Definition

An instance P of the data type *d3_plane* is an oriented plane in the three-dimensional space \mathbb{R}^3 . It can be defined by a triplet (a,b,c) of non-collinear points or a single point a and a normal vector v .

```
#include < LEDA/geo/d3_plane.h >
```

2. Creation

d3_plane p ; introduces a variable p of type *d3_plane* initialized to the xy-plane.

d3_plane $p(\text{const } d3_point\& a, \text{const } d3_point\& b, \text{const } d3_point\& c)$;

introduces a variable p of type *d3_plane* initialized to the plane through (a, b, c) .

Precondition: a , b , and c are not collinear.

d3_plane $p(\text{const } d3_point\& a, \text{const } vector\& v)$;

introduces a variable p of type *d3_plane* initialized to the plane that contains a with normal vector v .

Precondition: $v.dim() = 3$ and $v.length() > 0$.

d3_plane $p(\text{const } d3_point\& a, \text{const } d3_point\& b)$;

introduces a variable p of type *d3_plane* initialized to the plane that contains a with normal vector $b - a$.

3. Operations

d3_point $p.point1()$ returns the first point of p .

d3_point $p.point2()$ returns the second point of p .

d3_point $p.point3()$ returns the third point of p .

double $p.A()$ returns the A parameter of the plane equation.

double $p.B()$ returns the B parameter of the plane equation.

double $p.C()$ returns the C parameter of the plane equation.

double $p.D()$ returns the D parameter of the plane equation.

vector $p.normal()$ returns a normal vector of p .

- double* p .sqr_dist(*const d3_point& q*)
returns the square of the Euclidean distance between p and q .
- double* p .distance(*const d3_point& q*)
returns the Euclidean distance between p and q .
- int* p .cmp_distances(*const d3_point& p1*, *const d3_point& p2*)
compares the distances of $p1$ and $p2$ to p and returns the result.
- vector* p .normal_project(*const d3_point& q*)
returns the vector pointing from q to its projection on p along the normal direction.
- int* p .intersection(*const d3_point p1*, *const d3_point p2*, *d3_point& q*)
if the line l through $p1$ and $p2$ intersects p in a single point this point is assigned to q and the result is 1, if l and p do not intersect the result is 0, and if l is contained in p the result is 2.
- int* p .intersection(*const d3_plane& Q*, *d3_point& i1*, *d3_point& i2*)
if p and plane Q intersect in a line L then $(i1, i2)$ are assigned two different points on L and the result is 1, if p and Q do not intersect the result is 0, and if $p = Q$ the result is 2.
- d3_plane* p .translate(*double dx*, *double dy*, *double dz*)
returns p translated by vector (dx, dy, dz) .
- d3_plane* p .translate(*const vector& v*)
returns $p+v$, i.e., p translated by vector v .
Precondition: v .dim() = 3.
- d3_plane* $p +$ *const vector& v* returns p translated by vector v .
- d3_plane* p .reflect(*const d3_plane& Q*)
returns p reflected across plane Q .
- d3_plane* p .reflect(*const d3_point& q*)
returns p reflected across point q .
- d3_point* p .reflect_point(*const d3_point& q*)
returns q reflected across plane p .
- int* p .side_of(*const d3_point& q*)
computes the side of p on which q lies.

bool *p*.contains(*const d3_point& q*)

returns true if point *q* lies on plane *p*, i.e., (*p.side_of(q) == 0*), and false otherwise.

bool *p*.parallel(*const d3_plane& Q*)

returns true if planes *p* and *Q* are parallel and false otherwise.

ostream& *ostream& O* << *const d3_plane& p*

writes *p* to output stream *O*.

istream& *istream& I* >> *d3_plane& p*

reads the coordinates of *p* (six *double* numbers) from input stream *I*.

Non-Member Functions

int orientation(*const d3_plane& p, const d3_point& q*)

computes the orientation of *p.sideof(q)*.

17.6 Spheres in 3D-Space (`d3_sphere`)

1. Definition

An instance of the data type *d3_sphere* is an oriented sphere in 3d space. The sphere is defined by four points $p1, p2, p3, p4$ (*d3_points*).

```
#include < LEDA/geo/d3_sphere.h >
```

2. Creation

```
d3_sphere S(const d3_point& p1, const d3_point& p2, const d3_point& p3,  
            const d3_point& p4);
```

introduces a variable *S* of type *d3_sphere*. *S* is initialized to the sphere through points $p1, p2, p3, p4$.

3. Operations

<i>bool</i>	<i>S</i> .contains(const <i>d3_point</i> & <i>p</i>)	returns true, if <i>p</i> is on the sphere, false otherwise.
<i>bool</i>	<i>S</i> .inside(const <i>d3_point</i> & <i>p</i>)	returns true, if <i>p</i> is inside the sphere, false otherwise.
<i>bool</i>	<i>S</i> .outside(const <i>d3_point</i> & <i>p</i>)	returns true, if <i>p</i> is outside the sphere, false otherwise.
<i>d3_point</i>	<i>S</i> .point1()	returns $p1$.
<i>d3_point</i>	<i>S</i> .point2()	returns $p2$.
<i>d3_point</i>	<i>S</i> .point3()	returns $p3$.
<i>d3_point</i>	<i>S</i> .point4()	returns $p4$.
<i>bool</i>	<i>S</i> .is_degenerate()	returns true, if the 4 defining points are coplanar.
<i>d3_point</i>	<i>S</i> .center()	returns the center of the sphere.
<i>double</i>	<i>S</i> .sqr_radius()	returns the square of the radius.
<i>double</i>	<i>S</i> .radius()	returns the radius.
<i>double</i>	<i>S</i> .surface()	returns the size of the surface.
<i>double</i>	<i>S</i> .volume()	returns the volume of the sphere.
<i>d3_sphere</i>	<i>S</i> .translate(const <i>vector</i> & <i>v</i>)	returns <i>S</i> translated by vector <i>v</i> .

d3_sphere *S.translate(double dx, double dy, double dz)*
 returns *S* translated by vector (dx, dy, dz) .

17.7 Simplices in 3D-Space (`d3_simplex`)

1. Definition

An instance of the data type *d3_simplex* is a simplex in 3d space. The simplex is defined by four points $p1, p2, p3, p4$ (*d3_points*). We call the simplex degenerate, if the four defining points are coplanar.

```
#include < LEDA/geo/d3_simplex.h >
```

2. Types

```
d3_simplex::coord_type    the coordinate type (double).
```

```
d3_simplex::point_type    the point type (d3_point).
```

3. Creation

```
d3_simplex S(const d3_point& a, const d3_point& b, const d3_point& c,  
              const d3_point& d);  
             creates the simplex (a, b, c, d).
```

```
d3_simplex S;             creates the simplex ((0, 0, 0), (1, 0, 0), (0, 1, 0), (0, 0, 1)).
```

4. Operations

```
d3_point    S.point1()           returns p1.
```

```
d3_point    S.point2()           returns p2.
```

```
d3_point    S.point3()           returns p3.
```

```
d3_point    S.point4()           returns p4.
```

```
d3_point    S[int i]             returns pi. Precondition: i > 0 and i < 5.
```

```
int         S.index(const d3_point& p)  
             returns 1 if  $p == p1$ , 2 if  $p == p2$ , 3 if  $p == p3$ , 4 if  
 $p == p4$ , and 0 otherwise.
```

```
bool       S.is_degenerate()     returns true if S is degenerate and false otherwise.
```

```
d3_sphere S.circumscribing_sphere()  
             returns a d3_sphere through (p1, p2, p3, p4) (precon-  
dition: the d3_simplex is not degenerate).
```

```
bool       S.in_simplex(const d3_point& p)  
             returns true, if p is contained in the simplex.
```

<i>bool</i>	<i>S.insphere(const d3_point& p)</i>	returns true, if <i>p</i> lies in the interior of the sphere through <i>p1, p2, p3, p4</i> .
<i>double</i>	<i>S.vol()</i>	returns the signed volume of the simplex.
<i>d3_simplex</i>	<i>S.reflect(const d3_point& p, const d3_point& q, const d3_point& v)</i>	returns <i>S</i> reflected across the plane through (<i>p, q, v</i>).
<i>d3_simplex</i>	<i>S.reflect(const d3_point& p)</i>	returns <i>S</i> reflected across point <i>p</i> .
<i>d3_simplex</i>	<i>S.translate(const vector& v)</i>	returns <i>S</i> translated by vector <i>v</i> . <i>Precond. : v.dim() = 3.</i>
<i>d3_simplex</i>	<i>S.translate(double dx, double dy, double dz)</i>	returns <i>S</i> translated by vector (<i>dx, dy, dz</i>).
<i>d3_simplex</i>	<i>S + const vector& v</i>	returns <i>S</i> translated by vector <i>v</i> .
<i>d3_simplex</i>	<i>S - const vector& v</i>	returns <i>S</i> translated by vector $-v$.

17.8 Rational Points in 3D-Space (`d3_rat_point`)

1. Definition

An instance of data type `d3_rat_point` is a point with rational coordinates in the three-dimensional space. A point with cartesian coordinates (a, b, c) is represented by homogeneous coordinates (x, y, z, w) of arbitrary length integers (see 6.1) such that $a = x/w$, $b = y/w$, $c = z/w$ and $w > 0$.

```
#include < LEDA/geo/d3_rat_point.h >
```

2. Creation

`d3_rat_point p;` introduces a variable `p` of type `d3_rat_point` initialized to the point $(0, 0, 0)$.

`d3_rat_point p(const rational& a, const rational& b, const rational& c);`
introduces a variable `p` of type `d3_rat_point` initialized to the point (a, b, c) .

`d3_rat_point p(integer a, integer b, integer c);`
introduces a variable `p` of type `d3_rat_point` initialized to the point (a, b, c) .

`d3_rat_point p(integer x, integer y, integer z, integer w);`
introduces a variable `p` of type `d3_rat_point` initialized to the point with homogeneous coordinates (x, y, z, w) if $w > 0$ and to point $(-x, -y, -z, -w)$ if $w < 0$.
Precondition: $w \neq 0$.

`d3_rat_point p(const rat_vector& v);`
introduces a variable `p` of type `d3_rat_point` initialized to the point $(v[0], v[1], v[2])$.
Precondition: $v.dim() = 3$.

3. Operations

`d3_point p.to_float()` returns a floating point approximation of `p`.

`rat_vector p.to_vector()` returns the vector extending from the origin to `p`.

`integer p.X()` returns the first homogeneous coordinate of `p`.

`integer p.Y()` returns the second homogeneous coordinate of `p`.

`integer p.Z()` returns the third homogeneous coordinate of `p`.

<i>integer</i>	<i>p.W()</i>	returns the fourth homogeneous coordinate of <i>p</i> .
<i>double</i>	<i>p.XD()</i>	returns a floating point approximation of <i>p.X()</i> .
<i>double</i>	<i>p.YD()</i>	returns a floating point approximation of <i>p.Y()</i> .
<i>double</i>	<i>p.ZD()</i>	returns a floating point approximation of <i>p.Z()</i> .
<i>double</i>	<i>p.WD()</i>	returns a floating point approximation of <i>p.W()</i> .
<i>rational</i>	<i>p.xcoord()</i>	returns the <i>x</i> -coordinate of <i>p</i> .
<i>rational</i>	<i>p.ycoord()</i>	returns the <i>y</i> -coordinate of <i>p</i> .
<i>rational</i>	<i>p.zcoord()</i>	returns the <i>z</i> -coordinate of <i>p</i> .
<i>rational</i>	<i>p[int i]</i>	returns the <i>i</i> th cartesian coordinate of <i>p</i> <i>Precondition:</i> $0 \leq i \leq 2$.
<i>double</i>	<i>p.xcoordD()</i>	returns a floating point approximation of <i>p.xcoord()</i> .
<i>double</i>	<i>p.ycoordD()</i>	returns a floating point approximation of <i>p.ycoord()</i> .
<i>double</i>	<i>p.zcoordD()</i>	returns a floating point approximation of <i>p.zcoord()</i> .
<i>integer</i>	<i>p.hcoord(int i)</i>	returns the <i>i</i> th homogeneous coordinate of <i>p</i> . <i>Precondition:</i> $0 \leq i \leq 3$.
<i>rat_point</i>	<i>p.project_xy()</i>	returns <i>p</i> projected into the <i>xy</i> -plane.
<i>rat_point</i>	<i>p.project_yz()</i>	returns <i>p</i> projected into the <i>yz</i> -plane.
<i>rat_point</i>	<i>p.project_xz()</i>	returns <i>p</i> projected into the <i>xz</i> -plane.
<i>d3_rat_point</i>	<i>p.reflect(const d3_rat_point& p, const d3_rat_point& q, const d3_rat_point& r)</i>	returns <i>p</i> reflected across the plane passing through <i>p</i> , <i>q</i> and <i>r</i> . <i>Precondition:</i> <i>p</i> , <i>q</i> and <i>r</i> are not collinear.
<i>d3_rat_point</i>	<i>p.reflect(const d3_rat_point& q)</i>	returns <i>p</i> reflected across point <i>q</i> .
<i>d3_rat_point</i>	<i>p.translate(const rational& dx, const rational& dy, const rational& dz)</i>	returns <i>p</i> translated by vector (<i>dx</i> , <i>dy</i> , <i>dz</i>).
<i>d3_rat_point</i>	<i>p.translate(integer dx, integer dy, integer dz, integer dw)</i>	returns <i>p</i> translated by vector (<i>dx/dw</i> , <i>dy/dw</i> , <i>dz/dw</i>).

d3_rat_point p .translate(*const rat_vector*& v)

returns $p + v$, i.e., p translated by vector v
Precondition: v .dim() = 3.

d3_rat_point $p + \text{const rat_vector\& } v$

returns p translated by vector v
Precondition: v .dim() = 3.

d3_rat_point $p - \text{const rat_vector\& } v$

returns p translated by vector $-v$
Precondition: v .dim() = 3.

rational p .sqr_dist(*const d3_rat_point*& q)

returns the squared distance between p and q .

rational p .xdist(*const d3_rat_point*& q)

returns the x-distance between p and q .

rational p .ydist(*const d3_rat_point*& q)

returns the y-distance between p and q .

rational p .zdist(*const d3_rat_point*& q)

returns the z-distance between p and q .

rat_vector $p - \text{const d3_rat_point\& } q$

returns the difference vector of the coordinates.

ostream& *ostream*& $O \ll \text{const d3_rat_point\& } p$

writes the homogeneous coordinates (x, y, z, w) of p to output stream O .

istream& *istream*& $I \gg \text{d3_rat_point\& } p$

reads the homogeneous coordinates (x, y, z, w) of p from input stream I .

Non-Member Functions

- int* `orientation(const d3_rat_point& a, const d3_rat_point& b,`
 `const d3_rat_point& c, const d3_rat_point& d)`
 computes the orientation of points a , b , c and d as the
 sign of the determinant
- $$\begin{vmatrix} a_w & b_w & c_w & d_w \\ a_x & b_x & c_x & d_x \\ a_y & b_y & c_y & d_y \\ a_z & b_z & c_z & d_z \end{vmatrix}$$
- i.e., it returns +1 if point d lies left of the directed
 plane through a, b, c , 0 if a, b, c and d are coplanar, and
 −1 otherwise.
- int* `orientation_xy(const d3_rat_point& a, const d3_rat_point& b,`
 `const d3_rat_point& c)`
 returns the orientation of the projections of a , b and c
 into the xy -plane.
- int* `orientation_yz(const d3_rat_point& a, const d3_rat_point& b,`
 `const d3_rat_point& c)`
 returns the orientation of the projections of a , b and c
 into the yz -plane.
- int* `orientation_xz(const d3_rat_point& a, const d3_rat_point& b,`
 `const d3_rat_point& c)`
 returns the orientation of the projections of a , b and c
 into the xz -plane.
- int* `cmp_distances(const d3_rat_point& p1, const d3_rat_point& p2,`
 `const d3_rat_point& p3, const d3_rat_point& p4)`
 compares the distances $(p1, p2)$ and $(p3, p4)$. Returns
 +1 (−1) if distance $(p1, p2)$ is larger (smaller) than
 distance $(p3, p4)$, otherwise 0.
- d3_rat_point* `midpoint(const d3_rat_point& a, const d3_rat_point& b)`
 returns the midpoint of a and b .
- rational* `volume(const d3_rat_point& a, const d3_rat_point& b,`
 `const d3_rat_point& c, const d3_rat_point& d)`
 computes the signed volume of the simplex determined
 by a, b, c , and d , positive if $orientation(a, b, c, d) > 0$
 and negative otherwise.
- bool* `collinear(const d3_rat_point& a, const d3_rat_point& b,`
 `const d3_rat_point& c)`
 returns true if points a , b , c are collinear, and false
 otherwise.

- bool* `coplanar(const d3_rat_point& a, const d3_rat_point& b,
 const d3_rat_point& c, const d3_rat_point& d)`
 returns true if points a, b, c, d are coplanar and false otherwise.
- int* `side_of_sphere(const d3_rat_point& a, const d3_rat_point& b,
 const d3_rat_point& c, const d3_rat_point& d,
 const d3_rat_point& e)`
 returns $+1$ (-1) if point e lies on the positive (negative) side of the oriented sphere through points a, b, c , and d , and 0 if e is contained in this sphere.
- int* `region_of_sphere(const d3_rat_point& a, const d3_rat_point& b,
 const d3_rat_point& c, const d3_rat_point& d,
 const d3_rat_point& x)`
 determines whether the point x lies inside ($= +1$), on ($= 0$), or outside ($= -1$) the sphere through points a, b, c, d , (equivalent to $orientation(a, b, c, d) * side_of_sphere(a, b, c, d, x)$)
 Precondition: $orientation(A) \neq 0$
- bool* `contained_in_simplex(const d3_rat_point& a, const d3_rat_point& b,
 const d3_rat_point& c, const d3_rat_point& d,
 const d3_rat_point& x)`
 determines whether x is contained in the simplex spanned by the points a, b, c, d .
 Precondition: a, b, c, d are affinely independent.
- bool* `contained_in_simplex(const array<d3_rat_point>& A, const d3_rat_point& x)`
 determines whether x is contained in the simplex spanned by the points in A .
 Precondition: A must have size ≤ 4 and the points in A must be affinely independent.
- bool* `contained_in_affine_hull(const list<d3_rat_point>& L, const d3_rat_point& x)`
 determines whether x is contained in the affine hull of the points in L .
- bool* `contained_in_affine_hull(const array<d3_rat_point>& A,
 const d3_rat_point& x)`
 determines whether x is contained in the affine hull of the points in A .
- int* `affine_rank(const array<d3_rat_point>& L)`
 computes the affine rank of the points in L .
- int* `affine_rank(const array<d3_rat_point>& A)`
 computes the affine rank of the points in A .

- d3_rat_point* `random_d3_rat_point_in_unit_cube(int D = 16383)`
 returns a point whose coordinates are random rationals of the form i/D where i is a random integer in the range $[0..D]$. The default value of D is $2^{14} - 1$.
- void* `random_d3_rat_points_in_unit_cube(int n, int D, list<d3_rat_point>& L)`
 returns a list L of n points
- void* `random_d3_rat_points_in_unit_cube(int n, list<d3_rat_point>& L)`
 as above, but the default value of D is used.
- d3_rat_point* `random_d3_rat_point_in_ball(int R)`
 returns a random point with integer coordinates in the ball with radius R centered at the origin.
Precondition: $R \leq 2^{14}$.
- void* `random_d3_rat_points_in_ball(int n, int R, list<d3_rat_point>& L)`
 returns a list L of n points
- d3_rat_point* `random_d3_rat_point_in_unit_ball(int D = 16383)`
 returns a point in the unit ball whose coordinates are random rationals of the form i/D where i is a random integer in the range $[0..D]$. The default value of D is $2^{14} - 1$.
- void* `random_d3_rat_points_in_unit_ball(int n, int D, list<d3_rat_point>& L)`
 returns a list L of n points
- void* `random_d3_rat_points_in_unit_ball(int n, list<d3_rat_point>& L)`
 returns a list L of n points The default value of D is used.
- d3_rat_point* `random_d3_rat_point_in_disc(int R)`
 returns a random point with integer x and y -coordinates in the disc with radius R centered at the origin. The z -coordinate is zero. In 2d this is the same as the function `random_rat_point_in_ball`.
Precondition: $R \leq 2^{14}$.
- void* `random_d3_rat_points_in_disc(int n, int R, list<d3_rat_point>& L)`
 returns a list L of n points
- d3_rat_point* `random_d3_rat_point_on_circle(int R)`
 returns a random point with integer coordinates that lies close to the circle with radius R centered at the origin.
- void* `random_d3_rat_points_on_circle(int m, int R, list<d3_rat_point>& L)`
 returns a list L of n points

- d3_rat_point* `random_d3_rat_point_on_unit_circle(int D = 16383)`
 returns a point close to the unit circle whose coordinates are random rationals of the form i/D where i is a random integer in the range $[0..D]$. The default value of D is $2^{14} - 1$.
- void* `random_d3_rat_points_on_unit_circle(int m, int D, list<d3_rat_point>& L)`
 returns a list L of n points
- void* `random_d3_rat_points_on_unit_circle(int m, list<d3_rat_point>& L)`
 returns a list L of n points The default value of D is used.
- d3_rat_point* `random_d3_rat_point_on_sphere(int R)`
 returns a point with integer coordinates close to the sphere with radius R centered at the origin.
- void* `random_d3_rat_points_on_sphere(int m, int R, list<d3_rat_point>& L)`
 returns a list L of n points
- d3_rat_point* `random_d3_rat_point_on_unit_sphere(int D = 16383)`
 returns a point close to the unit sphere whose coordinates are random rationals of the form i/D where i is a random integer in the range $[0..D]$. The default value of D is $2^{14} - 1$. In 2d this function is equivalent to `point_on_unit_circle`.
- void* `random_d3_rat_points_on_unit_sphere(int m, int D, list<d3_rat_point>& L)`
 returns a list L of n points
- void* `random_d3_rat_points_on_unit_sphere(int m, list<d3_rat_point>& L)`
 returns a list L of n points The default value of D is used.
- d3_rat_point* `random_d3_rat_point_on_paraboloid(int maxc)`
 returns a point (x, y, z) with x and y random integers in the range $[-maxc..maxc]$, and $z = 0.004 * (x * x + y * y) - 1.25 * maxc$. The function does not make sense in 2d.
- void* `random_d3_rat_points_on_paraboloid(int n, int maxc, list<d3_rat_point>& L)`
 returns a list L of n points
- void* `lattice_d3_rat_points(int n, int maxc, list<d3_rat_point>& L)`
 returns a list L of approximately n points. The points have integer coordinates $id/maxc$ for an appropriately chosen d and $-maxc/d \leq i \leq maxc/d$.

void `random_d3_rat_points_on_segment(int n, int maxc, list<d3_rat_point>& L)`
generates n points on the diagonal whose coordinates
are random integer in the range from $-maxc$ to $maxc$.

17.9 Straight Rational Rays in 3D-Space (d3_rat_ray)

1. Definition

An instance r of the data type $d3_rat_ray$ is a directed straight ray defined by two points with rational coordinates in three-dimensional space.

```
#include < LEDA/geo/d3_rat_ray.h >
```

2. Creation

```
d3_rat_ray r(const d3_rat_point& p1, const d3_rat_point& p2);
```

introduces a variable r of type $d3_rat_ray$. r is initialized to the ray starting at point $p1$ and going through $p2$.

```
d3_rat_ray r(const d3_rat_segment& s);
```

introduces a variable r of type $d3_rat_ray$. r is initialized to $ray(s.source(), s.target())$.

3. Operations

```
d3_rat_point r.source() returns the source of  $r$ .
```

```
d3_rat_point r.point1() returns the source of  $r$ .
```

```
d3_rat_point r.point2() returns a point on  $r$  different from the source.
```

```
d3_rat_segment r.seg() returns a segment on  $r$ .
```

```
bool r.contains(const d3_rat_point& p)
returns true if  $p$  lies on  $r$ .
```

```
bool r.contains(const d3_rat_segment& s)
returns true if  $s$  lies on  $r$ .
```

```
bool r.intersection(const d3_rat_segment& s, d3_rat_point& inter)
if  $s$  and  $r$  intersect in a single point, true is returned
and the point of intersection is assigned to  $inter$ . Otherwise
false is returned.
```

```
bool r.intersection(const d3_rat_ray& r, d3_rat_point& inter)
if  $r$  and  $r$  intersect in a single point, true is returned
and the point of intersection is assigned to  $inter$ . Otherwise
false is returned.
```

<i>bool</i>	<i>r.project_xy(rat_ray& m)</i>	if the projection of <i>r</i> into the <i>xy</i> plane is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>bool</i>	<i>r.project_xz(rat_ray& m)</i>	if the projection of <i>r</i> into the <i>xz</i> plane is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>bool</i>	<i>r.project_yz(rat_ray& m)</i>	if the projection of <i>r</i> into the <i>yz</i> plane is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>bool</i>	<i>r.project(const d3_rat_point& p, const d3_rat_point& q, const d3_rat_point& v, d3_rat_ray& m)</i>	if the projection of <i>r</i> into the plane through (p, q, v) is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>d3_rat_ray</i>	<i>r.reverse()</i>	returns a <i>rat_ray</i> starting at <i>r.source()</i> with direction $-r.to_vector()$.
<i>d3_rat_ray</i>	<i>r.translate(const rat_vector& v)</i>	returns <i>r</i> translated by vector <i>v</i> . Precond. : $v.dim() = 3$.
<i>d3_rat_ray</i>	<i>r.translate(rational dx, rational dy, rational dz)</i>	returns <i>r</i> translated by vector (dx, dy, dz) .
<i>d3_rat_ray</i>	<i>r + const rat_vector& v</i>	returns <i>r</i> translated by vector <i>v</i> .
<i>d3_rat_ray</i>	<i>r - const rat_vector& v</i>	returns <i>r</i> translated by vector $-v$.
<i>d3_rat_ray</i>	<i>r.reflect(const d3_rat_point& p, const d3_rat_point& q, const d3_rat_point& v)</i>	returns <i>r</i> reflected across the plane through (p, q, v) .
<i>d3_rat_ray</i>	<i>r.reflect(const d3_rat_point& p)</i>	returns <i>r</i> reflected across point <i>p</i> .
<i>rat_vector</i>	<i>r.to_vector()</i>	returns $point2() - point1()$.

17.10 Rational Lines in 3D-Space (*d3_rat_line*)

1. Definition

An instance *l* of the data type *d3_rat_line* is a directed straight line in three-dimensional space.

```
#include < LEDA/geo/d3_rat_line.h >
```

2. Creation

```
d3_rat_line l(const d3_rat_point& p1, const d3_rat_point& p2);
```

introduces a variable *l* of type *d3_rat_line*. *l* is initialized to the line through points *p1*, *p2*.

```
d3_rat_line l(const d3_rat_segment& s);
```

introduces a variable *l* of type *d3_rat_line*. *l* is initialized to the line supporting segment *s*.

```
d3_rat_line l;
```

introduces a variable *l* of type *d3_rat_line*. *l* is initialized to the line through points (0, 0, 0, 1) and (1, 0, 0, 1).

3. Operations

```
d3_line l.to_float() returns a floating point approximation of l.
```

```
bool l.contains(const d3_rat_point& p)
returns true if p lies on l.
```

```
d3_rat_point l.point1() returns a point on l.
```

```
d3_rat_point l.point2() returns a second point on l.
```

```
d3_rat_segment l.seg() returns a segment on l.
```

```
bool l.project_xy(rat_line& m)
if the projection of l into the xy plane is not a point,
the function returns true and assigns the projection
to m. Otherwise false is returned.
```

```
bool l.project_xz(rat_line& m)
if the projection of l into the xz plane is not a point,
the function returns true and assigns the projection
to m. Otherwise false is returned.
```

<i>bool</i>	<i>l.project_yz(rat_line& m)</i>	if the projection of <i>l</i> into the <i>yz</i> plane is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>bool</i>	<i>l.project(const d3_rat_point& p, const d3_rat_point& q, const d3_rat_point& v, d3_rat_line& m)</i>	if the projection of <i>l</i> into the plane through (p, q, v) is not a point, the function returns true and assigns the projection to <i>m</i> . Otherwise false is returned.
<i>d3_rat_line</i>	<i>l.translate(integer dx, integer dy, integer dz, integer dw)</i>	returns <i>l</i> translated by vector $(dx/dw, dy/dw, dz/dw)$.
<i>d3_rat_line</i>	<i>l.translate(rat_vector v)</i>	returns <i>l</i> translated by <i>v</i> . <i>Precond.</i> : $v.dim() = 3$.
<i>d3_rat_line</i>	<i>l + const rat_vector& v</i>	returns <i>l</i> translated by vector <i>v</i> .
<i>d3_rat_line</i>	<i>l - const rat_vector& v</i>	returns <i>l</i> translated by vector $-v$.
<i>d3_rat_line</i>	<i>l.reflect(const d3_rat_point& p, const d3_rat_point& q, const d3_rat_point& v)</i>	returns <i>l</i> reflected across the plane through (p, q, v) .
<i>d3_rat_line</i>	<i>l.reflect(const d3_rat_point& p)</i>	returns <i>l</i> reflected across point <i>p</i> .
<i>d3_rat_line</i>	<i>l.reverse()</i>	returns <i>l</i> reversed.
<i>rat_vector</i>	<i>l.to_vector()</i>	returns $point2() - point1()$.
<i>bool</i>	<i>l.intersection(const d3_rat_segment& s)</i>	decides, whether <i>l</i> and <i>s</i> intersect in a single point.
<i>bool</i>	<i>l.intersection(const d3_rat_segment& s, d3_rat_point& p)</i>	decides, whether <i>l</i> and <i>s</i> intersect in a single point. If so, the point of intersection is assigned to <i>p</i> .
<i>bool</i>	<i>l.intersection(const d3_rat_line& m)</i>	decides, whether <i>l</i> and <i>m</i> intersect in a single point.

bool *l.intersection(const d3_rat_line& m, d3_rat_point& p)*
 decides, whether *l* and *m* intersect in a single point.
 If so, the point of intersection is assigned to *p*.

rational *l.sqr_dist(const d3_rat_point& p)*
 returns the square of the distance between *l* and *p*.

17.11 Rational Segments in 3D-Space (`d3_rat_segment`)

1. Definition

An instance s of the data type `d3_rat_segment` is a directed straight line segment in three-dimensional space, i.e., a line segment connecting two rational points $p, q \in \mathbb{R}^3$. p is called the *source* or start point and q is called the *target* or end point of s . A segment is called *trivial* if its source is equal to its target. If s is not trivial, we use $line(s)$ to denote the straight line containing s .

```
#include < LEDA/geo/d3_rat_segment.h >
```

2. Creation

```
d3_rat_segment  $s(const\ d3\_rat\_point\&\ p1,\ const\ d3\_rat\_point\&\ p2);$ 
```

introduces a variable S of type `d3_rat_segment`. S is initialized to the segment through points $p1, p2$.

```
d3_rat_segment  $s;$  introduces a variable  $S$  of type d3_rat_segment.  $S$  is initialized to the segment through points  $(0, 0, 0, 1)$  and  $(1, 0, 0, 1)$ .
```

3. Operations

```
d3_segmet  $s.to\_float()$  returns a floating point approximation of  $s$ .
```

```
bool  $s.contains(const\ d3\_rat\_point\&\ p)$   
decides whether  $s$  contains  $p$ .
```

```
d3_rat_point  $s.source()$  returns the source point of segment  $s$ .
```

```
d3_rat_point  $s.target()$  returns the target point of segment  $s$ .
```

```
rational  $s.xcoord1()$  returns the x-coordinate of  $s.source()$ .
```

```
rational  $s.xcoord2()$  returns the x-coordinate of  $s.target()$ .
```

```
rational  $s.ycoord1()$  returns the y-coordinate of  $s.source()$ .
```

```
rational  $s.ycoord2()$  returns the y-coordinate of  $s.target()$ .
```

```
rational  $s.zcoord1()$  returns the z-coordinate of  $s.source()$ .
```

```
rational  $s.zcoord2()$  returns the z-coordinate of  $s.target()$ .
```

```
rational  $s.dx()$  returns  $xcoord2() - xcoord1()$ .
```

<i>rational</i>	<code>s.dy()</code>	returns $ycoord2() - ycoord1()$.
<i>rational</i>	<code>s.dz()</code>	returns $zcoord2() - zcoord1()$.
<i>rat_segment</i>	<code>s.project_xy()</code>	returns the projection into the xy plane.
<i>rat_segment</i>	<code>s.project_xz()</code>	returns the projection into the xz plane.
<i>rat_segment</i>	<code>s.project_yz()</code>	returns the projection into the yz plane.
<i>d3_rat_segment</i>	<code>s.project(const d3_rat_point& p, const d3_rat_point& q, const d3_rat_point& v)</code>	returns s projected into the plane through (p, q, v) .
<i>d3_rat_segment</i>	<code>s.reflect(const d3_rat_point& p, const d3_rat_point& q, const d3_rat_point& v)</code>	returns s reflected across the plane through (p, q, v) .
<i>d3_rat_segment</i>	<code>s.reflect(const d3_rat_point& p)</code>	returns s reflected across point p .
<i>d3_rat_segment</i>	<code>s.reverse()</code>	returns s reversed.
<i>rat_vector</i>	<code>s.to_vector()</code>	returns $S.target() - S.source()$.
<i>bool</i>	<code>s.intersection(const d3_rat_segment& t)</code>	decides, whether s and t intersect in a single point.
<i>bool</i>	<code>s.intersection(const d3_rat_segment& t, d3_rat_point& p)</code>	decides, whether s and t intersect. If they intersect in a single point, the point is assigned to p
<i>bool</i>	<code>s.intersection_of_lines(const d3_rat_segment& t, d3_rat_point& p)</code>	If $line(s)$ and $line(t)$ intersect in a single point this point is assigned to p and the result is true, otherwise the result is false.
<i>bool</i>	<code>s.is_trivial()</code>	returns true if s is trivial.
<i>rational</i>	<code>s.sqr_length()</code>	returns the square of the length of s .
<i>d3_rat_segment</i>	<code>s.translate(const rat_vector& v)</code>	returns s translated by vector v . <i>Precond.</i> : $v.dim() = 3$.
<i>d3_rat_segment</i>	<code>s.translate(rational dx, rational dy, rational dz)</code>	returns s translated by vector (dx, dy, dz) .
<i>d3_rat_segment</i>	<code>s.translate(integer dx, integer dy, integer dz, integer dw)</code>	returns s translated by vector $(dx/dw, dy/dw, dz/w)$.

d3_rat_segment s + const rat_vector& v

returns *s* translated by vector *v*.

d3_rat_segment s - const rat_vector& v

returns *s* translated by vector $-v$.

17.12 Rational Planes (d3_rat_plane)

1. Definition

An instance P of the data type *d3_rat_plane* is an oriented rational plane in the three-dimensional space \mathbb{R}^3 . It can be defined by a triplet (a,b,c) of non-collinear rational points or a single rational point a and a normal vector v .

```
#include < LEDA/geo/d3_rat_plane.h >
```

2. Creation

d3_rat_plane p ; introduces a variable p of type *d3_rat_plane* initialized to the trivial plane.

d3_rat_plane $p(\text{const } d3_rat_point\& a, \text{const } d3_rat_point\& b, \text{const } d3_rat_point\& c)$;
introduces a variable p of type *d3_rat_plane* initialized to the plane through (a, b, c) .
Precondition: $a, b,$ and c are not collinear.

d3_rat_plane $p(\text{const } d3_rat_point\& a, \text{const } rat_vector\& v)$;
introduces a variable p of type *d3_rat_plane* initialized to the plane that contains a with normal vector v .
Precondition: $v.dim() = 3$ and $v.length() > 0$.

d3_rat_plane $p(\text{const } d3_rat_point\& a, \text{const } d3_rat_point\& b)$;
introduces a variable p of type *d3_rat_plane* initialized to the plane that contains a with normal vector $b - a$.

3. Operations

d3_rat_point $p.point1()$ returns the first point of p .

d3_rat_point $p.point2()$ returns the second point of p .

d3_rat_point $p.point3()$ returns the third point of p .

integer $p.A()$ returns the A parameter of the plane equation.

integer $p.B()$ returns the B parameter of the plane equation.

integer $p.C()$ returns the C parameter of the plane equation.

integer $p.D()$ returns the D parameter of the plane equation.

rat_vector $p.normal()$ returns a normal vector of p .

- d3_plane* $p.to_float()$ returns a floating point approximation of p .
- rational* $p.sqr_dist(const\ d3_rat_point\&\ q)$
 returns the square of the Euclidean distance between p and q .
- rat_vector* $p.normal_project(const\ d3_rat_point\&\ q)$
 returns the vector pointing from q to its projection on p along the normal direction.
- int* $p.intersection(const\ d3_rat_point\ p1,\ const\ d3_rat_point\ p2,$
 $d3_rat_point\&\ q)$
 if the line l through $p1$ and $p2$ intersects p in a single point this point is assigned to q and the result is 1, if l and p do not intersect the result is 0, and if l is contained in p the result is 2.
- int* $p.intersection(const\ d3_rat_plane\&\ Q,\ d3_rat_point\&\ i1,\ d3_rat_point\&\ i2)$
 if p and plane Q intersect in a line L then $(i1, i2)$ are assigned two different points on L and the result is 1, if p and Q do not intersect the result is 0, and if $p = Q$ the result is 2.
- d3_rat_plane* $p.translate(const\ rational\&\ dx,\ const\ rational\&\ dy,\ const\ rational\&\ dz)$
 returns p translated by vector (dx, dy, dz) .
- d3_rat_plane* $p.translate(integer\ dx,\ integer\ dy,\ integer\ dz,\ integer\ dw)$
 returns p translated by vector $(dx/dw, dy/dw, dz/dw)$.
- d3_rat_plane* $p.translate(const\ rat_vector\&\ v)$
 returns $p+v$, i.e., p translated by vector v .
 Precondition: $v.dim() = 3$.
- d3_rat_plane* $p + const\ rat_vector\&\ v$
 returns p translated by vector v .
- d3_rat_plane* $p.reflect(const\ d3_rat_plane\&\ Q)$
 returns p reflected across plane Q .
- d3_rat_plane* $p.reflect(const\ d3_rat_point\&\ q)$
 returns p reflected across point q .
- d3_rat_point* $p.reflect_point(const\ d3_rat_point\&\ q)$
 returns q reflected across plane p .
- int* $p.side_of(const\ d3_rat_point\&\ q)$
 computes the side of p on which q lies.

bool *p.contains(const d3_rat_point& q)*
 returns true if point *q* lies on plane *p*, i.e.,
 (*p.side_of(q) == 0*), and false otherwise .

bool *p.parallel(const d3_rat_plane& Q)*
 returns true if planes *p* and *Q* are parallel, and false
 otherwise.

ostream& *ostream& O << const d3_rat_plane& p*
 writes *p* to output stream *O*.

istream& *istream& I >> d3_rat_plane& p*
 reads *p* from input stream *I*.

Non-Member Functions

int *orientation(const d3_rat_plane& p, const d3_rat_point& q)*
 computes the orientation of *p.sideof(q)*.

17.13 Rational Spheres (`d3_rat_sphere`)

1. Definition

An instance of the data type `d3_rat_sphere` is an oriented sphere in 3d space. The sphere is defined by four points p_1, p_2, p_3, p_4 with rational coordinates (`d3_rat_points`).

```
#include < LEDA/geo/d3_rat_sphere.h >
```

2. Creation

```
d3_rat_sphere  $S(\text{const } d3\_rat\_point\& p_1, \text{const } d3\_rat\_point\& p_2,$   

 $\text{const } d3\_rat\_point\& p_3, \text{const } d3\_rat\_point\& p_4);$   

introduces a variable  $S$  of type d3_rat_sphere.  $S$  is initialized to the  

sphere through points  $p_1, p_2, p_3, p_4$ .
```

3. Operations

```
d3_sphere  $S.to\_float()$  returns a floating point approximation of  $S$ .
```

```
bool  $S.contains(\text{const } d3\_rat\_point\& p)$   

returns true, if  $p$  is on the sphere, false otherwise.
```

```
bool  $S.inside(\text{const } d3\_rat\_point\& p)$   

returns true, if  $p$  is inside the sphere, false otherwise.
```

```
bool  $S.outside(\text{const } d3\_rat\_point\& p)$   

returns true, if  $p$  is outside the sphere, false otherwise.
```

```
d3_rat_point  $S.point1()$  returns  $p_1$ .
```

```
d3_rat_point  $S.point2()$  returns  $p_2$ .
```

```
d3_rat_point  $S.point3()$  returns  $p_3$ .
```

```
d3_rat_point  $S.point4()$  returns  $p_4$ .
```

```
bool  $S.is\_degenerate()$  returns true, if the 4 defining points are coplanar.
```

```
d3_rat_point  $S.center()$  returns the center of the sphere.
```

```
rational  $S.sqr\_radius()$  returns the square of the radius.
```

```
d3_rat_sphere  $S.translate(\text{const } rat\_vector\& v)$   

translates the sphere by vector  $v$  and returns a new  

d3_rat_sphere.
```

d3_rat_sphere *S*.translate(*const rational& r1*, *const rational& r2*, *const rational& r3*)

translates the sphere by vector (r1,r2,r3) and returns
a new *d3_rat_sphere*.

17.14 Rational Simplices (`d3_rat_simplex`)

1. Definition

An instance of the data type `d3_rat_simplex` is a simplex in 3d space. The simplex is defined by four points $p1, p2, p3, p4$ with rational coordinates (`d3_rat_points`). We call the simplex degenerate, if the four defining points are coplanar.

```
#include < LEDA/geo/d3_rat_simplex.h >
```

2. Types

`d3_rat_simplex::coord_type` the coordinate type (*rational*).

`d3_rat_simplex::point_type` the point type (*d3_rat_point*).

3. Creation

`d3_rat_simplex` $S(\text{const } d3_rat_point\& a, \text{const } d3_rat_point\& b, \text{const } d3_rat_point\& c, \text{const } d3_rat_point\& d);$
creates the simplex (a, b, c, d) .

`d3_rat_simplex` $S;$ creates the simplex $((0, 0, 0), (1, 0, 0), (0, 1, 0), (0, 0, 1))$.

4. Operations

`d3_simplex` $S.to_d3_simplex()$ returns a floating point approximation of S .

`d3_rat_point` $S.point1()$ returns $p1$.

`d3_rat_point` $S.point2()$ returns $p2$.

`d3_rat_point` $S.point3()$ returns $p3$.

`d3_rat_point` $S.point4()$ returns $p4$.

`d3_rat_point` $S[int i]$ returns pi . *Precondition:* $i > 0$ and $i < 5$.

`int` $S.index(\text{const } d3_rat_point\& p)$
returns 1 if $p == p1$, 2 if $p == p2$, 3 if $p == p3$, 4 if $p == p4$, 0 otherwise.

`bool` $S.is_degenerate()$ returns true if S is degenerate and false otherwise.

`d3_rat_sphere` $S.circumscribing_sphere()$
returns a `d3_rat_sphere` through $(p1, p2, p3, p4)$ (precondition: the `d3_rat_simplex` is not degenerate).

- bool* $S.in_simplex(const\ d3_rat_point\&\ p)$
returns true, if p is contained in the simplex.
- bool* $S.insphere(const\ d3_rat_point\&\ p)$
returns true, if p lies in the interior of the sphere through $p1, p2, p3, p4$.
- rational* $S.vol()$ returns the signed volume of the simplex.
- d3_rat_simplex* $S.reflect(const\ d3_rat_point\&\ p, const\ d3_rat_point\&\ q, const\ d3_rat_point\&\ v)$
returns S reflected across the plane through (p, q, v) .
- d3_rat_simplex* $S.reflect(const\ d3_rat_point\&\ p)$
returns S reflected across point p .
- d3_rat_simplex* $S.translate(const\ rat_vector\&\ v)$
returns S translated by vector v .
Precond. : $v.dim() = 3$.
- d3_rat_simplex* $S.translate(rational\ dx, rational\ dy, rational\ dz)$
returns S translated by vector (dx, dy, dz) .
- d3_rat_simplex* $S.translate(integer\ dx, integer\ dy, integer\ dz, integer\ dw)$
returns S translated by vector $(dx/dw, dy/dw, dz/w)$.
- d3_rat_simplex* $S + const\ rat_vector\&\ v$
returns S translated by vector v .
- d3_rat_simplex* $S - const\ rat_vector\&\ v$
returns S translated by vector $-v$.

17.15 3D Convex Hull Algorithms (`d3_hull`)

void CONVEX_HULL(*const list*<*d3_rat_point*>& *L*, *GRAPH*<*d3_rat_point*, *int*>& *H*)

CONVEX_HULL takes as argument a list of points and returns the (planar embedded) surface graph *H* of the convex hull of *L*. The algorithm is based on an incremental space sweep. The running time is $O(n^2)$ in the worst case and $O(n \log n)$ for most inputs.

bool CHECK_HULL(*const GRAPH*<*d3_rat_point*, *int*>& *H*)

a checker for convex hulls.

void CONVEX_HULL(*const list*<*d3_point*>& *L*, *GRAPH*<*d3_point*, *int*>& *H*)

a floating point version of *CONVEX_HULL*.

bool CHECK_HULL(*const GRAPH*<*d3_point*, *int*>& *H*)

a checker for floating-point convex hulls.

17.16 3D Triangulation and Voronoi Diagram Algorithms (d3_delaunay)

void D3TRIANG(*const list*<d3_rat_point>& *L*, *GRAPH*<d3_rat_point, int>& *G*)
computes a triangulation *G* of the points in *L*.

void D3DELAUNAY(*const list*<d3_rat_point>& *L*, *GRAPH*<d3_rat_point, int>& *G*)
computes a delaunay triangulation *G* of the points in *L*.

void D3VORONOI(*const list*<d3_rat_point>& *L0*, *GRAPH*<d3_rat_sphere, int>& *G*)
computes the voronoi diagramm *G* of the points in *L*.

Chapter 18

Graphics

This section describes the data types *color*, *window*, *panel*, and *menu*.

18.1 Colors (`color`)

1. Definition

The data type *color* is the type of all colors available for drawing operations in windows (cf. 18.2). Each color is defined by a triple of integers (r, g, b) with $0 \leq r, g, b \leq 255$, the so-called *rgb-value* of the color. The number of available colors is restricted and depends on the underlying hardware. Colors can be created from rgb-values, from names in a color data base (X11), or from the 16 integer constants (enumeration in `<LEDA/graphics/x_window.h>`) *black*, *white*, *red*, *green*, *blue*, *yellow*, *violet*, *orange*; *cyan*, *brown*, *pink*, *green2*, *blue2*, *grey1*, *grey2*, *grey3*.

```
#include <LEDA/graphics/color.h >
```

2. Creation

`color col;` creates a color with rgb-value $(0, 0, 0)$ (i.e. black).

`color col(int r, int g, int b);`
creates a color with rgb-value (r, g, b) .

`color col(const char * name);`
creates a color and initializes it with the rgb-value of color *name* from the X11 color data base $((0, 0, 0)$ if *name* does not exist).

`color col(int i);` creates a color and initializes it with one of the 16 predefined colors. Here *i* is one of the 16 integer constants *black*, *white*, *red*, *green*, *blue*, *yellow*, *violet*, *orange*, *cyan*, *brown*, *pink*, *green2*, *blue2*, *grey1*, *grey2*, or *grey3*.

3. Operations

- void* `col.set_rgb(int r, int g, int b)` sets the rgb-value of *col* to (r, g, b) .
- void* `col.get_rgb(int& r, int& g, int& b)`
assigns the rgb-value of *col* to (r, g, b) .
- void* `col.set_red(int r)` changes the r-value of *col* to *r*.
- void* `col.set_green(int g)` changes the g-value of *col* to *g*.
- void* `col.set_blue(int b)` changes the b-value of *col* to *b*.

18.2 Windows (window)

1. Definition

The data type *window* provides an interface for graphical input and output of basic two-dimensional geometric objects. Application programs using this data type have to be linked with *libW.a* and (on UNIX systems) with the X11 base library *libX11.a* (cf. section 1.6):

```
CC prog.c -lW -lP -lG -lL -lX11 -lm
```

An instance W of type *window* is an iso-oriented rectangular window in the two-dimensional plane. The default representation of W on the screen is a square of maximal possible edge length positioned in the upper right corner of the display.

In general, a window consists of two rectangular sections, a *panel section* in the upper part and a *drawing section* in the rest of the window. The panel section contains *panel items* such as sliders, choice fields, string items and buttons. They have to be created before the window is opened by special panel operations described in section 18.2.

The drawing section can be used for the output of geometric objects such as points, lines, segments, arrows, circles, polygons, graph, . . . and for the input of all these objects using the mouse input device. All drawing and input operations in the drawing section use a coordinate system that is defined by three parameters of type *double*: $xmin$, the minimal x-coordinate, $xmax$, the maximal x-coordinate, and $ymin$, the minimal y-coordinate. The two parameters $xmin$ and $xmax$ define the scaling factor *scaling* as $w/(xmax - xmin)$, where w is the width of the drawing section in pixels. The maximal y-coordinate $ymax$ of the drawing section is equal to $ymin + h \cdot scaling$ and depends on the actual shape of the window on the screen. Here, h is the height of the drawing section in pixels.

A list of all window parameters:

1. The *foreground color* parameter (default *black*) defines the default color to be used in all drawing operations. There are 18 predefined colors (enumeration in <LEDA/graphics/x_window.h>): *black*, *white*, *red*, *green*, *blue*, *yellow*, *violet*, *orange*, *cyan*, *brown*, *pink*, *green2*, *blue2*, *grey1*, *grey2*, *grey3* *ivory*, and *invisible*. Note that all drawing operations have an optional color argument that can be used to override the default foreground color. On monochrome systems all colors different from *white* are displayed as *black*. The color *invisible* can be used for invisible (transparent) objects.
2. The *background color* parameter (default *white*) defines the default background color (e.g. used by $W.clear()$).
3. The *text font* parameter defines the name of the font to be used in all text drawing operations.

4. Minimal and maximal coordinates of the drawing area *xmin* (default 0), *xmax* (default 100), *ymin* (default 0).
5. The *grid dist* parameter (default 0) defines the width of the grid that is used in the drawing area. A grid width of 0 indicates that no grid is to be used.
6. The *frame label* parameter defines a string to be displayed in the frame of the window.
7. The *show coordinates* flag (default *true*) determines whether the current coordinates of the mouse cursor in the drawing section are displayed in the upper right corner.
8. The *flush output* flag (default *true*) determines whether the graphics output stream is flushed after each draw action.
9. The *line width* parameter (default value 1 pixel) defines the width of all kinds of lines (segments, arrows, edges, circles, polygons).
10. The *line style* parameter defines the style of lines. Possible line styles are *solid* (default), *dashed*, and *dotted*.
11. The *point style* parameter defines the style points are drawn by the *draw_point* operation. Possible point styles are *pixel_point*, *cross_point* (default), *plus_point*, *circle_point*, *disc_point*, *rect_point*, and *box_point*.
12. The *node width* parameter (default value 8 pixels) defines the diameter of nodes created by the *draw_node* and *draw_filled_node* operations.
13. The *text mode* parameter defines how text is inserted into the window. Possible values are *transparent* (default) and *opaque*.
14. The *show orientation* parameter defines, whether or not the direction or orientation of segments, lines, rays, triangles, polygons and *gen_polygons* will be shown (default *false*.)
15. The *drawing mode* parameter defines the logical operation that is used for setting pixels in all drawing operations. Possible values are *src_mode* (default) and *xor_mode*. In *src_mode* pixels are set to the respective color value, in *xor_mode* the value is bitwise added to the current pixel value.
16. The *redraw function* parameter is a pointer to a function of type `void (*F)(window*)`. It is called with a pointer to the corresponding window as argument to redraw (parts of) the window whenever a redrawing is necessary, e.g., if the shape of the window is changed or previously hidden parts of it become visible.
17. The *window delete handler* parameter is a pointer to a function of type `void (*F)(window*)`. It is called with a pointer to the corresponding window as argument when the window is to be closed by the window manager (e.g. by pressing the ×-button on Windows-NT systems). The default window delete handler closes the window and terminates the program.

18. The *buttons per line* parameter (default ∞) defines the maximal number of buttons in one line of the panel section.
19. The *precision* parameter (default 16) defines the precision that is used for representing window coordinates, more precisely, all x and y coordinates generated by window input operations are doubles whose mantissa are truncated after *precision* - 1 bits after the binary point.

In addition to call-back (handler) functions LEDA windows now also support the usage of function objects. Function object classes have to be derived from the *window_handler* base class.

```
class window_handler {
    ...
    virtual void operator()() { }

    // parameter access functions
    double get_double(int nr) const;
    int     get_int() const;
    window* get_window_ptr() const;
    char*   get_char_ptr() const;
};
```

Derived classes have to implement the handling function in the definition of the *operator()* method. The different *get_* methods can be called to retrieve parameters.

If both, a handler function and an object for the same action is supplied the object has higher priority.

```
#include < LEDA/graphics/window.h >
```

2. Creation

window W ; creates a squared window with maximal possible edge length (minimum of width and height of the display).

window $W(const\ char\ * label)$;
 creates a maximal squared window with frame label *label*.

window $W(int\ w,\ int\ h)$;
 creates a window W of physical size w pixels \times h pixels .

window $W(int\ w,\ int\ h,\ const\ char\ * label)$;
 creates a window W of physical size w pixels \times h pixels and frame label *label*.

All four variants initialize the coordinates of W to $xmin = 0$, $xmax = 100$ and $ymin = 0$. The *init* operation (see below) can later be used to change the window coordinates and scaling. Please note, that a window is not displayed before the function *display* is called for it.

3. Operations

3.1 Initialization

<i>void</i>	$W.init(double\ x_0, double\ x_1, double\ y_0)$	sets $xmin$ to x_0 , $xmax$ to x_1 , and $ymin$ to y_0 , the scaling factor $scaling$ to $w/(xmax - xmin)$, and $ymax$ to $ymin + h/scaling$. Here w and h are the width and height of the drawing section in pixels.
<i>void</i>	$W.init_rectangle(double\ x_0, double\ x_1, double\ y_0, double\ y_1)$	adjusts the window such that the points (x_0, y_0) and (x_1, y_1) are contained in the drawing section.
<i>double</i>	$W.set_grid_dist(double\ d)$	sets the grid distance of W to d .
<i>grid_style</i>	$W.set_grid_style(grid_style\ s)$	sets the grid style of W to s .
<i>int</i>	$W.set_grid_mode(int\ d)$	sets the grid distance of W to d pixels.
<i>int</i>	$W.set_precision(int\ prec)$	sets the precision of W to $prec$.
<i>void</i>	$W.init(double\ x_0, double\ x_1, double\ y_0, int\ d, bool\ erase = true)$	same as $W.init(x_0, x_1, y_0)$ followed by $W.set_grid_mode(d)$. If the optional flag <i>erase</i> is set to <i>false</i> the window will not be erased.
<i>void</i>	$W.display()$	opens W and displays it at the center of the screen. Note that $W.display()$ has to be called before all drawing operations and that all operations adding panel items to W (cf. 18.2) have to be called before the first call of $W.display()$.

- void* *W.display(int x, int y)* opens *W* and displays it with its left upper corner at position (x, y) . Special values for *x* and *y* are *window :: min*, *window :: center*, and *window :: max* for positioning *W* at the minimal or maximal *x* or *y* coordinate or centering it in the *x* or *y* dimension.
- void* *W.display(window& W₀, int x, int y)*
 opens *W* and displays it with its left upper corner at position (x, y) relative to the upper left corner of window *W₀*.

W.open... can be used as a synonym for *W.display...* Note, that the *open* operation for panels (cf. 18.3) is defined slightly different.

- void* *W.close()* closes *W* by removing it from the display.
- void* *W.clear()* clears *W* using the current background color or pixmap, i.e., if *W* has a background pixmap defined it is tiled with *P* such that the upper left corner is the tiling origin. Otherwise, it is filled with background color of *W*.
- void* *W.clear(double x₀, double y₀, double x₁, double y₁)*
 only clears the rectangular area (x_0, y_0, x_1, y_1) of window *W* using the current background color or pixmap.
- void* *W.clear(color c)* clears *W* with color *c* and sets the background color of *W* to *c*.
- void* *W.clear(double xorig, double yorig)*
 clears *W*. If a background pixmap is defined the point $(xorig, yorig)$ is used as the origin of tiling.
- void* *W.redraw()* repaints the drawing area if *W* has a redraw function.

3.2 Setting parameters

- color* *W.set_color(color c)* sets the foreground color parameter to *c* and returns its previous value.
- color* *W.set_fill_color(color c)* sets the fill color parameter (used by \ll operators) to *c* and returns its previous value.
- color* *W.set_bg_color(color c)* sets the background color parameter to *c* and returns its previous value.

<i>char*</i>	<i>W.set_bg_pixmap(char * pr)</i>	sets the background pixmap to <i>pr</i> and returns its previous value.
<i>int</i>	<i>W.set_line_width(int pix)</i>	sets the line width parameter to <i>pix</i> pixels and returns its previous value.
<i>line_style</i>	<i>W.set_line_style(line_style s)</i>	sets the line style parameter to <i>s</i> and returns its previous value.
<i>int</i>	<i>W.set_node_width(int pix)</i>	sets the node width parameter to <i>pix</i> pixels and returns its previous value.
<i>text_mode</i>	<i>W.set_text_mode(text_mode m)</i>	sets the text mode parameter to <i>m</i> and returns its previous value.
<i>drawing_mode</i>	<i>W.set_mode(drawing_mode m)</i>	sets the drawing mode parameter to <i>m</i> and returns its previous value.
<i>int</i>	<i>W.set_cursor(int cursor_id = -1)</i>	sets the mouse cursor of <i>W</i> to <i>cursor_id</i> . Here <i>cursor_id</i> must be one of the constants predefined in <code><X₁₁/cursorfont.h></code> or <code>-1</code> for the system default cursor. Returns the previous cursor.
<i>void</i>	<i>W.set_show_coordinates(bool b)</i>	sets the show coordinates flag to <i>b</i> .
<i>bool</i>	<i>W.set_show_orientation(bool orient)</i>	sets the show orientation parameter to <i>orient</i> .
<i>void</i>	<i>W.set_frame_label(string s)</i>	makes <i>s</i> the window frame label.
<i>void</i>	<i>W.set_icon_label(string s)</i>	makes <i>s</i> the window icon label.
<i>void</i>	<i>W.reset_frame_label()</i>	restores the standard LEDA frame label.
<i>void</i>	<i>W.set_window_delete_handler(void (*F)(window*))</i>	sets the window delete handler function parameter to <i>F</i> .

- void* `W.set_window_delete_object(const window_handler& obj)`
sets the window delete object parameter to *obj*.
- void* `W.set_show_coord_handler(void (*F)(window*, double, double))`
sets the show coordinate handler function parameter to *F*.
- void* `W.set_show_coord_object(const window_handler& obj)`
sets the show coordinate object parameter to *obj*.
- void* `W.set_redraw(void (*F)(window*))`
sets the redraw function parameter to *F*.
- void* `W.set_redraw(const window_handler& obj)`
sets the redraw object parameter to *obj*.
- void* `W.set_redraw(void (*F)(window*, double, double, double, double) = 0)`
sets the redraw function parameter to *F*.
- void* `W.set_redraw2(const window_handler& obj)`
sets the redraw object parameter to *obj*.
- void* `W.set_bg_redraw(void (*F)(window*, double, double, double, double) = 0)`
sets the background redraw function parameter to *F*.
- void* `W.set_bg_redraw(const window_handler& obj)`
sets the background redraw object parameter to *obj*.
- void* `W.start_timer(int msec, void (*F)(window*))`
starts a timer that runs *F* every *msec* milliseconds with a pointer to *W*.
- void* `W.start_timer(int msec, const window_handler& obj)`
starts a timer that runs the *operator()* of *obj* every *msec* milliseconds.
- void* `W.stop_timer()` stops the timer.
- void* `W.set_flush(bool b)` sets the flush parameter to *b*.
- void* `W.set_icon_pixrect(char * pr)`
makes *pr* the new icon of *W*.

<i>GraphWin*</i>	<i>W</i> .get_graphwin()	returns a pointer to the <i>GraphWin</i> (see 18.6) that uses <i>W</i> as its display window or <i>NULL</i> if <i>W</i> is not used by any <i>GraphWin</i> .
<i>GeoWinTypeName*</i>	<i>W</i> .get_geowin()	returns a pointer to the <i>GeoWin</i> (see Section 18.8) that uses <i>W</i> as its display window or <i>NULL</i> if <i>W</i> is not used by any <i>GeoWin</i> .
<i>int</i>	<i>W</i> .width()	returns the width of <i>W</i> in pixels.
<i>int</i>	<i>W</i> .height()	returns the height of <i>W</i> in pixels.
<i>int</i>	<i>W</i> .menu_bar_height()	returns the height of the menu bar of <i>W</i> in pixels and 0 if <i>W</i> has no menu bar (see <i>W.make_menu_bar()</i>).
<i>int</i>	<i>W</i> .xpos()	returns the x-coordinate of the upper left corner of the frame of <i>W</i> .
<i>int</i>	<i>W</i> .ypos()	returns the y-coordinate of the upper left corner of the frame of <i>W</i> .
<i>int</i>	<i>W</i> .get_state()	returns the state of <i>W</i> .
<i>void</i>	<i>W</i> .set_state(<i>int stat</i>)	sets the state of <i>W</i> to <i>stat</i> .
<i>bool</i>	<i>W</i> .contains(<i>const point& p</i>)	returns true if <i>p</i> lies in the drawing area.

3.4 Drawing Operations

All drawing operations have an optional color argument at the end of the parameter list. If this argument is omitted the current foreground color (cf. section 18.2) of *W* is used.

3.4.1 Drawing points

<i>void</i>	<i>W</i> .draw_point(<i>double x, double y, color c = window::fgcol</i>)	draws the point (<i>x, y</i>) (a cross of two short segments).
<i>void</i>	<i>W</i> .draw_point(<i>const point& p, color c = window::fgcol</i>)	draws point <i>p</i> .
<i>void</i>	<i>W</i> .draw_pixel(<i>double x, double y, color c = window::fgcol</i>)	sets the color of the pixel at position (<i>x, y</i>) to <i>c</i> .
<i>void</i>	<i>W</i> .draw_pixel(<i>const point& p, color c = window::fgcol</i>)	sets the color of the pixel at position <i>p</i> to <i>c</i> .
<i>void</i>	<i>W</i> .draw_pixels(<i>const list<point>& L, color c = window::fgcol</i>)	sets the color of all pixels in <i>L</i> to <i>c</i> .

void *W.draw_pixels(int n, double * xcoord, double * ycoord, color c = window::fgcol)*
 draws all pixels $(xcoord[i], ycoord[i])$ for $0 \leq i \leq n - 1$.

3.4.2 Drawing line segments

void *W.draw_segment(double x₁, double y₁, double x₂, double y₂, color c = window::fgcol)*
 draws a line segment from (x_1, y_1) to (x_2, y_2) .

void *W.draw_segment(const point& p, const point& q, color c = window::fgcol)*
 draws a line segment from point *p* to point *q*.

void *W.draw_segment(const segment& s, color c = window::fgcol)*
 draws line segment *s*.

void *W.draw_segment(point p, point q, line l, color c = window::fgcol)*
 draws the part of the line *l* between *p* and *q*. This version of *draw_segment* should be used if *p* or *q* may lie far outside *W*. *Precondition*: *p* and *q* lie on *l* or at least close to *l*.

void *W.draw_segments(const list<segment>& L, color c = window::fgcol)*
 draws all segments in *L*.

3.4.3 Drawing lines

void *W.draw_line(double x₁, double y₁, double x₂, double y₂, color c = window::fgcol)*
 draws a straight line passing through points (x_1, y_1) and (x_2, y_2) .

void *W.draw_line(const point& p, const point& q, color c = window::fgcol)*
 draws a straight line passing through points *p* and *q*.

void *W.draw_line(const segment& s, color c = window::fgcol)*
 draws the line supporting segment *s*.

void *W.draw_line(const line& l, color c = window::fgcol)*
 draws line *l*.

void *W.draw_hline(double y, color c = window::fgcol)*
 draws a horizontal line with y-coordinate *y*.

void *W.draw_vline(double x, color c = window::fgcol)*
 draws a vertical line with x-coordinate *x*.

3.4.4 Drawing Rays

void *W.draw_ray(double x₁, double y₁, double x₂, double y₂, color c = window::fgcol)*
 draws a ray starting in (x_1, y_1) and passing through (x_2, y_2) .

void *W.draw_ray(const point& p, const point& q, color c = window::fgcol)*
 draws a ray starting in *p* and passing through *q*.

void *W.draw_ray(const segment& s, color c = window::fgcol)*
 draws a ray starting in *s.source()* containing *s*.

void *W.draw_ray(const ray& r, color c = window::fgcol)*
 draws ray *r*.

void *W.draw_ray(point p, point q, line l, color c = window::fgcol)*
 draws the part of the line *l* on the ray with source *p* and passing through *q*. This version of *draw_ray* should be used if *p* may lie far outside *W*. *Precondition*: *p* and *q* lie on *l* or at least close to *l*.

3.4.5 Drawing Arcs and Curves

void *W.draw_arc(const point& p, const point& q, const point& r, color c = window::fgcol)*
 draws a circular arc starting in *p* passing through *q* and ending in *r*.

void *W.draw_bezier(const list<point>& C, int n, color c = window::fgcol)*
 draws the bezier curve with control polygon *C* by a polyline with *n* points.

void *W.draw_spline(const list<point>& L, int n, color c = window::fgcol)*
 draws a spline curve through the points of *L*. Each segment is approximated by a polyline with *m* points.

void *W.draw_closed_spline(const list<point>& L, int n, color c = window::fgcol)*
 draws a *closed* spline through the points of *L*.

void *W.draw_spline(const polygon& P, int n, color c = window::fgcol)*
 draws a *closed* spline through the vertices of *P*.

3.4.6 Drawing arrows

void *W.draw_arrow(double x₁, double y₁, double x₂, double y₂, color c = window::fgcol)*
 draws an arrow pointing from (x_1, y_1) to (x_2, y_2) .

void *W.draw_arrow(const point& p, const point& q, color c = window::fgcol)*
 draws an arrow pointing from point *p* to point *q*.

void *W.draw_arrow(const segment& s, color = window::fgcol)*
 draws an arrow pointing from *s.start()* to *s.end()*.

void *W.draw_polyline_arrow(const list<point>& lp, color c = window::fgcol)*
 draws a polyline arrow with vertex sequence *lp*.

void *W.draw_arc_arrow(const point& p, const point& q, const point& r,*
color c = window::fgcol)
 draws a circular arc arrow starting in *p* passing through *q*
 and ending in *r*.

void *W.draw_bezier_arrow(const list<point>& C, int n, color c = window::fgcol)*
 draws the bezier curve with control polygon *C* by a poly-
 line with *n* points, the last segment is drawn as an arrow.

void *W.draw_spline_arrow(const list<point>& L, int n, color c = window::fgcol)*
 draws a spline curve through the points of *L*. Each seg-
 ment is approximated by a polyline with *n* points. The
 last segment is drawn as an arrow.

point *W.draw_arrow_head(const point& p, double dir, color c = window::fgcol)*
 draws an arrow head at position *p* pointing to direction
dir, where *dir* is an angle from $[0, 2\pi]$.

3.4.7 Drawing circles

void *W.draw_circle(double x, double y, double r, color c = window::fgcol)*
 draws the circle with center (x, y) and radius *r*.

void *W.draw_circle(const point& p, double r, color c = window::fgcol)*
 draws the circle with center *p* and radius *r*.

void *W.draw_circle(const circle& C, color c = window::fgcol)*
 draws circle *C*.

void *W.draw_ellipse(double x, double y, double r₁, double r₂, color c = window::fgcol)*
 draws the ellipse with center (x, y) and radii *r₁* and *r₂*.

void *W.draw_ellipse(const point& p, double r₁, double r₂, color c = window::fgcol)*
 draws the ellipse with center *p* and radii *r₁* and *r₂*.

3.4.8 Drawing discs

void *W.draw_disc(double x, double y, double r, color c = window::fgcol)*
 draws a filled circle with center (x, y) and radius *r*.

void *W.draw_disc(const point& p, double r, color c = window::fgcol)*
 draws a filled circle with center *p* and radius *r*.

void *W.draw_disc(const circle& C, color c = window::fgcol)*
 draws filled circle *C*.

void *W.draw_filled_circle(double x, double y, double r, color c = window::fgcol)*
draws a filled circle with center (x, y) and radius r .

void *W.draw_filled_circle(const point& p, double r, color c = window::fgcol)*
draws a filled circle with center p and radius r .

void *W.draw_filled_circle(const circle& C, color c = window::fgcol)*
draws filled circle C .

void *W.draw_filled_ellipse(double x, double y, double r₁, double r₂,
color c = window::fgcol)*
draws a filled ellipse with center (x, y) and radii r_1 and r_2 .

void *W.draw_filled_ellipse(const point& p, double r₁, double r₂,
color c = window::fgcol)*
draws a filled ellipse with center p and radii r_1 and r_2 .

3.4.9 Drawing polygons

void *W.draw_polyline(const list<point>& lp, color c = window::fgcol)*
draws a polyline with vertex sequence lp .

void *W.draw_polyline(int n, double * xc, double * yc, color c = window::fgcol)*
draws a polyline with vertex sequence $(xc[0], yc[0]), \dots, (xc[n - 1], yc[n - 1])$.

void *W.draw_polygon(const list<point>& lp, color c = window::fgcol)*
draws the polygon with vertex sequence lp .

void *W.draw_oriented_polygon(const list<point>& lp, color c = window::fgcol)*
draws the polygon with vertex sequence lp and indicates the orientation by an arrow.

void *W.draw_polygon(const polygon& P, color c = window::fgcol)*
draws polygon P .

void *W.draw_oriented_polygon(const polygon& P, color c = window::fgcol)*
draws polygon P and indicates the orientation by an arrow.

void *W.draw_filled_polygon(const list<point>& lp, color c = window::fgcol)*
draws the filled polygon with vertex sequence lp .

void *W.draw_filled_polygon(const polygon& P, color c = window::fgcol)*
draws filled polygon P .

void *W.draw_polygon(const gen_polygon& P, color c = window::fgcol)*
draws polygon P .

- void* `W.draw_oriented_polygon(const gen_polygon& P, color c = window::fgcol)`
draws polygon P and indicates the orientation by an arrow.
- void* `W.draw_filled_polygon(const gen_polygon& P, color c = window::fgcol)`
draws filled polygon P .
- void* `W.draw_rectangle(double x0, double y0, double x1, double y1, color = window::fgcol)`
draws a rectangle with lower left corner (x_0, y_0) and upper right corner (x_1, y_1) .
Precondition: $x_0 < x_1$ and $y_0 < y_1$.
- void* `W.draw_rectangle(point p, point q, color = window::fgcol)`
draws a rectangle with lower left corner p and upper right corner q .
Precondition: $p < q$.
- void* `W.draw_rectangle(const rectangle& R, color = window::fgcol)`
draws rectangle R .
- void* `W.draw_box(double x0, double y0, double x1, double y1, color c = window::fgcol)`
draws a filled rectangle with lower left corner (x_0, y_0) and upper right corner (x_1, y_1) .
Precondition: $x_0 < x_1$ and $y_0 < y_1$.
- void* `W.draw_filled_rectangle(point p, point q, color = window::fgcol)`
draws a filled rectangle with lower left corner p and upper right corner q .
Precondition: $p < q$.
- void* `W.draw_filled_rectangle(const rectangle& R, color = window::fgcol)`
draws rectangle R .
- void* `W.draw_box(point p, point q, color c = window::fgcol)`
same as `draw_filled_rectangle(p, q, c)`.
- void* `W.draw_box(const rectangle& R, color c = window::fgcol)`
same as `draw_filled_rectangle(p, q, c)`.
- void* `W.draw_roundrect(double x0, double y0, double x1, double y1, double rndness, color col = window::fgcol)`
draws a rectangle (x_0, y_0, x_1, y_1) with round corners. The *rndness* argument must be a real number in the interval $[0, 1]$ and defines the “roundness” of the rectangle.
- void* `W.draw_roundrect(point p, point q, double rndness, color col = window::fgcol)`
draws a round rectangle with lower left corner p , upper right corner q , and roundness *rndness*.

void *W.draw_roundbox(double x₀, double y₀, double x₁, double y₁, double rndness, color col = window::fgcol)*
 draws a filled rectangle (x_0, y_0, x_1, y_1) with round corners. The *rndness* argument must be a real number in the interval $[0, 1]$ and defined the “roundness” of the rectangle.

void *W.draw_roundbox(point p, point q, double rndness, color col = window::fgcol)*
 draws a round filled rectangle with lower left corner *p*, upper right corner *q*, and roundness *rndness*.

void *W.draw_triangle(point a, point b, point c, color = window::fgcol)*
 draws triangle (a, b, c) .

void *W.draw_triangle(const triangle& T, color = window::fgcol)*
 draws triangle *T*.

void *W.draw_filled_triangle(point a, point b, point c, color = window::fgcol)*
 draws filled triangle (a, b, c) .

void *W.draw_filled_triangle(const triangle& T, color = window::fgcol)*
 draws filled triangle *T*.

3.4.10 Drawing functions

void *W.plot_xy(double x₀, double x₁, win_draw_func F, color c = window::fgcol)*
 draws the graph of function *F* in the x-range $[x_0, x_1]$, i.e., all pixels (x, y) with $y = F(x)$ and $x_0 \leq x \leq x_1$.

void *W.plot_yx(double y₀, double y₁, win_draw_func F, color c = window::fgcol)*
 draws the graph of function *F* in the y-range $[y_0, y_1]$, i.e., all pixels (x, y) with $x = F(y)$ and $y_0 \leq y \leq y_1$.

3.4.11 Drawing text

void *W.draw_text(double x, double y, string s, color c = window::fgcol)*
 writes string *s* starting at position (x, y) .

void *W.draw_text(const point& p, string s, color c = window::fgcol)*
 writes string *s* starting at position *p*.

void *W.draw_ctext(double x, double y, string s, color c = window::fgcol)*
 writes string *s* centered at position (x, y) .

void *W.draw_ctext(const point& p, string s, color c = window::fgcol)*
 writes string *s* centered at position *p*.

void *W.draw_ctext(string s, color c = window::fgcol)*
 writes string *s* centered in window *W*.

double `W.text_box(double x0, double x1, double y, string s, bool draw = true)`

formats and writes string *s* into a box with its left border at x-coordinate *x*₀, its right border at *x*₁, and its upper border at y-coordinate *y*. Some LaTeX-like formatting commands can be used: `\bf`, `\tt`, `\rm`, `\n`, `\c`, `\<color>`, ... returns y-coordinate of lower border of box. If the optional last parameter *draw* is set to *false* no drawing takes place and only the lower y-coordinate of the box is computed.

void `W.text_box(string s)` as above with *x*₀ = `W.xmin()`, *x*₁ = `W.xmax()`, and *y* = `W.ymax()`.

void `W.message(string s)` displays the message *s* (each call adds a new line).

void `W.del_message()` deletes the text written by all previous message operations.

3.4.12 Drawing nodes

Nodes are represented by circles of diameter *node_width*.

void `W.draw_node(double x0, double y0, color c = window::fgcol)`
draws a node at position (*x*₀, *y*₀).

void `W.draw_node(const point& p, color c = window::fgcol)`
draws a node at position *p*.

void `W.draw_filled_node(double x0, double y0, color c = window::bgcol)`
draws a filled node at position (*x*₀, *y*₀).

void `W.draw_filled_node(const point& p, color c = window::bgcol)`
draws a filled node at position *p*.

void `W.draw_text_node(double x, double y, string s, color c = window::bgcol)`
draws a node with label *s* at position (*x*, *y*).

void `W.draw_text_node(const point& p, string s, color c = window::bgcol)`
draws a node with label *s* at position *p*.

void `W.draw_int_node(double x, double y, int i, color c = window::bgcol)`
draws a node with integer label *i* at position (*x*, *y*).

void `W.draw_int_node(const point& p, int i, color c = window::bgcol)`
draws a node with integer label *i* at position *p*.

3.4.13 Drawing edges

Edges are drawn as straight line segments or arrows with a clearance of *node_width*/2 at each end.

void *W.draw_edge(double x₁, double y₁, double x₂, double y₂, color c = window::fgcol)*
draws an edge from (x_1, y_1) to (x_2, y_2) .

void *W.draw_edge(const point& p, const point& q, color c = window::fgcol)*
draws an edge from *p* to *q*.

void *W.draw_edge(const segment& s, color c = window::fgcol)*
draws an edge from *s.start()* to *s.end()*.

void *W.draw_edge_arrow(double x₁, double y₁, double x₂, double y₂,
color c = window::fgcol)*
draws a directed edge from (x_1, y_1) to (x_2, y_2) .

void *W.draw_edge_arrow(const point& p, const point& q, color c = window::fgcol)*
draws a directed edge from *p* to *q*.

void *W.draw_edge_arrow(const segment& s, color c = window::fgcol)*
draws a directed edge from *s.start()* to *s.end()*.

3.4.14 Bitmaps and Pixrects

*char** *W.create_bitmap(int w, int h, unsigned char * bm_data)*
creates a bitmap (monochrome pixrect) of width *w*, height *h*, from the bits in *data*.

*char** *W.create_pixrect(int w, int h, unsigned int bgra)*
creates a a solid pixrect of width *w* und height *h*.

*char** *W.create_pixrect(const char **xpm_str)*
creates a pixrect from the **xpm** data string *xpm_str*.

*char** *W.create_pixrect(string xpm_file)*
creates a pixrect from the **xpm** file *xpm_file*.

*char** *W.create_pixrect(int w, int h, unsigned char * bm_data, int fg = window::fgcol,
int bg = window::bgcol)*
creates a pixrect of width *w*, height *h*, foreground color *fg*, and background color *bg* from bitmap *data*.

*char** *W.get_pixrect(double x₁, double y₁, double x₂, double y₂)*
creates a color pixrect of width $w = x_2 - x_1$, height $h = y_2 - y_1$, and copies all pixels from the rectangular area (x_1, x_2, y_1, y_2) of *W* into it.

*char** *W.get_window_pixrect()*
creates a pixrect copy of the current window contents.

- int* `W.get_pixrect_width(char * pr)`
returns the width (number of pixels in a row) of pixrect *pr*.
- int* `W.get_pixrect_height(char * pr)`
returns the height (number of pixels in a column) of pixrect *pr*.
- void* `W.put_pixrect(double x, double y, char * pr)`
copies the contents of pixrect *pr* with lower left corner at position (x, y) into *W*.
- void* `W.put_pixrect(point p, char * pr)`
copies the contents of pixrect *pr* with lower left corner at position *p* into *W*.
- void* `W.center_pixrect(double x, double y, char * pr)`
copies the contents of pixrect *pr* into *W* such that its center lies on position (x, y) .
- void* `W.center_pixrect(char * pr)`
copies the contents of pixrect *pr* into *W* such that its center lies on the center of *W*.
- void* `W.put_pixrect(char * pr)`
copies pixrect *pr* with lower left corner at position $(W.xmin(), W.ymin())$ into *W*.
- void* `W.set_pixrect(char * pr)`
copies pixrect *pr* with upper left corner at position $(0, 0)$ into *W*.
- void* `W.fit_pixrect(char * pr)` scales pixrect *pr* to fit into *W*.
- void* `W.put_bitmap(double x, double y, char * bm, color c = window::fgcol)`
draws all pixels corresponding to 1-bits in *bm* with color *c*, here the lower left corner of *bm* corresponds to the pixel at position (x, y) in *W*.
- void* `W.put_pixrect(double x, double y, char * pr, int x0, int y0, int w, int h)`
copies (pixel) rectangle $(x_0, y_0, x_0 + w, y_0 + h)$ of *pr* with lower left corner at position (x, y) into *W*.
- void* `W.del_bitmap(char * bm)`
destroys bitmap *bm*.
- void* `W.del_pixrect(char * pr)`
destroys pixrect *pr*.

void *W.copy_rect(double x₀, double y₀, double x₁, double y₁, double x, double y)*
 copies all pixels of rectangle (x_0, y_0, x_1, y_1) into the rectangle $(x, y, x + w, y + h)$, where $w = x_1 - x_0$ and $h = y_1 - y_0$.

void *W.screenshot(string fname, bool full_color = true)*
 creates a screenshot of the current window. On unix systems suffix *.ps* is appended to *fname* and the output format is postscript. On windows systems the suffix *.wmf* is added and the format is windows metafile. If the flag *full_color* is set to *false* colors will be translated into grey scales.

3.4.15 Buffering

void *W.start_buffering()* starts buffering mode for *W*. If *W* has no associated buffer a buffer pixrect *buf* of the same size as the current drawing area of *W* is created. All subsequent drawing operations draw into *buf* instead of *W* until buffering mode is ended by calling *W.stop_buffering()*.

void *W.flush_buffer()* copies the contents of the buffer pixrect into the drawing area of *W*.

void *W.flush_buffer(double dx, double dy)*
 copies the contents of the buffer pixrect translated by vector (dx, dy) into the drawing area of *W*.

void *W.flush_buffer(double x₀, double y₀, double x₁, double y₁)*
 copies the contents of rectangle (x_0, y_0, x_1, y_1) of the buffer pixrect into the corresponding rectangle of the drawin area.

void *W.flush_buffer(double dx, double dy, double x₀, double y₀, double x₁, double y₁)*
 copies the contents of rectangle (x_0, y_0, x_1, y_1) of the buffer pixrect into the corresponding rectangle of the drawin area translated by vector (dx, dy) .

void *W.stop_buffering()* ends buffering mode.

void *W.stop_buffering(char * & prect)*
 ends buffering mode and returns the current buffer pixrect in *prect*.

3.4.16 Clipping

void *W.set_clip_rectangle(double x₀, double y₀, double x₁, double y₁)*
 sets the clipping region of *W* to rectangle (x_0, y_0, x_1, y_1) .

void *W.set_clip_ellipse(double x₀, double y₀, double r₁, double r₂)*
 sets the clipping region of *W* to ellipse with center (x, y) and horizontal radius *r1* and vertical radius *r2*.

void `W.reset_clipping()` restores the clipping region to the entire drawing area of *W*.

3.5 Input

The main input operation for reading positions, mouse clicks, and buttons from a window *W* is the operation `W.read_mouse()`. This operation is blocking, i.e., waits for a button to be pressed which is either a “real” button on the mouse device pressed inside the drawing area of *W* or a button in the panel section of *W*. In both cases, the number of the selected button is returned. Mouse buttons have pre-defined numbers `MOUSE_BUTTON(1)` for the left button, `MOUSE_BUTTON(2)` for the middle button, and `MOUSE_BUTTON(3)` for the right button. The numbers of the panel buttons can be defined by the user. If the selected button has an associated action function or sub-window this function/window is executed/opened (cf. 18.2 for details).

There is also a non-blocking version `W.get_mouse()` which returns the constant `NO_BUTTON` if no button was pressed.

The window data type also provides two more general input operations `W.read_event()` and `W.get_event()` for reading events. They return the event type (enumeration in `<LEDA/graphics/x_window.h>`), the value of the event, the position of the event in the drawing section, and a time stamp of the event.

3.5.1 Read Mouse

int `W.read_mouse()` waits until a mouse button is pressed inside of the drawing area or until a button of the panel section is selected. In both cases, the number *n* of the button is returned which is one of the predefined constants `MOUSE_BUTTON(i)` with $i \in \{1, 2, 3\}$ for mouse buttons and a user defined value (defined when adding the button with `W.button()`) for panel buttons. If the button has an associated action function this function is called with parameter *n*. If the button has an associated window *M* it is opened and `M.read_mouse()` is returned.

int `W.read_mouse(double& x, double& y)`
If a button is pressed inside the drawing area the current position of the cursor is assigned to (x, y) . The operation returns the number of the pressed button (see `W.read_mouse()`.)

int `W.read_mouse(point& p)`
as above, the current position is assigned to point *p*.

- int* `W.read_mouse_seg(double x0, double y0, double& x, double& y)`
displays a line segment from (x_0, y_0) to the current cursor position until a mouse button is pressed inside the drawing section of W . When a button is pressed the current position is assigned to (x, y) and the number of the pressed button is returned.
- int* `W.read_mouse_seg(const point& p, point& q)`
as above with $x_0 = p.xcoord()$ and $y_0 = p.ycoord()$ and the current position is assigned to q .
- int* `W.read_mouse_line(double x0, double y0, double& x, double& y)`
displays a line passing through (x_0, y_0) and the current cursor position until a mouse button is pressed inside the drawing section of W . When a button is pressed the current position is assigned to (x, y) and the number of the pressed button is returned.
- int* `W.read_mouse_line(const point& p, point& q)`
as above with $x_0 = p.xcoord()$ and $y_0 = p.ycoord()$ and the current position is assigned to q .
- int* `W.read_mouse_ray(double x0, double y0, double& x, double& y)`
displays a ray from (x_0, y_0) passing through the current cursor position until a mouse button is pressed inside the drawing section of W . When a button is pressed the current position is assigned to (x, y) and the number of the pressed button is returned.
- int* `W.read_mouse_ray(const point& p, point& q)`
as above with $x_0 = p.xcoord()$ and $y_0 = p.ycoord()$ and the current position is assigned to q .
- int* `W.read_mouse_rect(double x0, double y0, double& x, double& y)`
displays a rectangle with diagonal from (x_0, y_0) to the current cursor position until a mouse button is pressed inside the drawing section of W . When a button is pressed the current position is assigned to (x, y) and the number of the pressed button is returned.
- int* `W.read_mouse_rect(const point& p, point& q)`
as above with $x_0 = p.xcoord()$ and $y_0 = p.ycoord()$ and the current position is assigned to q .

- int* `W.read_mouse_circle(double x0, double y0, double& x, double& y)`
 displays a circle with center (x_0, y_0) passing through the current cursor position until a mouse button is pressed inside the drawing section of W . When a button is pressed the current position is assigned to (x, y) and the number of the pressed button is returned.
- int* `W.read_mouse_circle(const point& p, point& q)`
 as above with $x_0 = p.xcoord()$ and $y_0 = p.ycoord()$ and the current position is assigned to q .
- int* `W.read_mouse_arc(double x0, double y0, double x1, double y1, double& x, double& y)`
 displays an arc that starts in (x_0, y_0) , ends in (x_1, y_1) and passes through the current cursor position. When a mouse button is pressed inside the drawing section of W , the current position is assigned to (x, y) and the number of the pressed button is returned.
- int* `W.read_mouse_arc(const point& p, const point& q, point& r)`
 as above with $(x_0, y_0) = p$ and $(x_1, y_1) = q$ and the current position is assigned to r .
- int* `W.get_mouse()` non-blocking read operation, i.e., if a button was pressed its number is returned, otherwise the constant `NO_BUTTON` is returned.
- int* `W.get_mouse(double& x, double& y)`
 if a mouse button was pressed the corresponding position is assigned to (x, y) and the button number is returned, otherwise the constant `NO_BUTTON` is returned.
- int* `W.get_mouse(point& p)` if a mouse button was pressed the corresponding position is assigned to p and the button number is returned, otherwise the constant `NO_BUTTON` is returned.
- int* `W.read_mouse(double& x0, double& y0, int timeout1, int timeout2, bool& double_click, bool& drag)`
 ...
- int* `W.read_mouse(point& p, int timeout1, int timeout2, bool& double_click, bool& drag)`
 ...

3.5.2 Events

- int* `W.readEvent(int& val, double& x, double& y, unsigned long& t)`
 waits for next event in window *W* and returns it. Assigns the button or key to *val*, the position in *W* to (x, y) , and the time stamp of the event to *t*. Possible events are (cf. <LEDA/graphics/x_window.h>): `key_press_event`, `key_release_event`, `button_press_event`, `button_release_event`, `configure_event`, `motion_event`, `destroy_event`.
- int* `W.readEvent(int& val, double& x, double& y, unsigned long& t, int timeout)`
 as above, but waits only *timeout* milliseconds; if no event occurred the special event *no_event* is returned.
- int* `W.readEvent(int& val, double& x, double& y)`
 waits for next event in window *W* and returns it. Assigns the button or key to *val* and the position in *W* to (x, y) .
- int* `W.readEvent()` waits for next event in window *W* and returns it.
- int* `W.get_event(int& val, double& x, double& y)`
 if there is an event for window *W* in the event queue a *W.read_event* operation is performed, otherwise the integer constant *no_event* is returned.
- bool* `W.shift_key_down()` returns *true* if a *shift* key was pressed during the last handled mouse button event.
- bool* `W.ctrl_key_down()` returns *true* if a *ctrl* key was pressed during the last handled mouse button event.
- bool* `W.alt_key_down()` returns *true* if an *alt* key was pressed during the last handled mouse button event.
- int* `W.button_press_time()` returns the time-stamp (in msec) of the last button press event.
- int* `W.button_release_time()`
 returns the time-stamp (in msec) of the last button release event.

3.6 Panel Input

The operations listed in this section are useful for simple input of strings, numbers, and Boolean values.

- bool* `W.confirm(string s)` displays string *s* and asks for confirmation. Returns *true* iff the answer was “yes”.
- void* `W.acknowledge(string s)`
 displays string *s* and asks for acknowledgement.

- int* `W.read_panel(string h, int n, string * S)` displays a panel with header *h* and an array of *n* buttons with labels $S[0..n - 1]$, returns the index of the selected button.
- int* `W.read_vpanel(string h, int n, string * S)` like `read_panel` with vertical button layout.
- string* `W.read_string(string p)` displays a panel with prompt *p* for string input, returns the input.
- double* `W.read_real(string p)` displays a panel with prompt *p* for double input returns the input.
- int* `W.read_int(string p)` displays a panel with prompt *p* for integer input, returns the input.

3.7 Input and output operators

For input and output of basic geometric objects in the plane such as points, lines, line segments, circles, and polygons the `<<` and `>>` operators can be used. Similar to C++input streams windows have an internal state indicating whether there is more input to read or not. Its initial value is true and it is turned to false if an input sequence is terminated by clicking the right mouse button (similar to ending stream input by the eof character). In conditional statements, objects of type *window* are automatically converted to boolean by returning this internal state. Thus, they can be used in conditional statements in the same way as C++input streams. For example, to read a sequence of points terminated by a right button click, use “ **while** (`W >> p`) { ... } ”.

3.7.1 Output

- window&* `W << const point& p` like `W.draw_point(p)`.
- window&* `W << const segment& s`
like `W.draw_segment(s)`.
- window&* `W << const ray& r` like `W.draw_ray(r)`.
- window&* `W << const line& l` like `W.draw_line(l)`.
- window&* `W << const circle& C` like `W.draw_circle(C)`.
- window&* `W << const polygon& P`
like `W.draw_polygon(P)`.
- window&* `W << const gen_polygon& P`
like `W.draw_polygon(P)`.

<i>int</i>	<code>get_mouse(window * & w, double& x, double& y)</code>	non-blocking variant of <code>read_mouse</code> , returns <code>NO_BUTTON</code> if no button was pressed.
<i>void</i>	<code>put_back_event()</code>	puts last handled event back to the event queue.

3.9 Panel Operations

The panel section of a window is used for displaying text messages and for updating the values of variables. It consists of a list of panel items and a list of buttons. The operations in this section add panel items or buttons to the panel section of W . Note that they have to be called before the window is displayed the first time.

In general, a panel item consists of a string label and an associated variable of a certain type (`int`, `bool`, `string`, `double`, `color`). The value of this variable can be manipulated through the item. Each button has a label (displayed on the button) and an associated number. The number of a button is either defined by the user or is the rank of the button in the list of all buttons. If a button is pressed (i.e. selected by a mouse click) during a `read_mouse` operation its number is returned.

Action functions can be associated with buttons and some items (e.g. slider items) whenever a button with an associated action function is pressed this function is called with the number of the button as actual parameter. Action functions of items are called whenever the value of the corresponding variable is changed with the new value as actual parameter. All action functions must have the type `void func(int)`.

Another way to define a button is to associate another window with it. In this case the button will have a menu sign and as soon as it is pressed the attached window will open. This method can be used to implement pop-up menus. The return value of the current `read_mouse` operation will be the number associated with the button in the menu.

3.9.1 General Settings

<i>void</i>	<code>W.set_panel_bg_color(color c)</code>	sets the background color of the panel area to c .
<i>void</i>	<code>W.buttons_per_line(int n)</code>	defines the maximal number n of buttons per line.
<i>void</i>	<code>W.set_button_space(int s)</code>	sets the space between to adjacent buttons to s pixels.
<i>void</i>	<code>W.set_item_height(int h)</code>	sets the vertical size of all items to h pixels.

- panel_item* `W.pstyle_item(string s, point_style& x, const char * hlp = 0)`
 adds a point style item with label *s* and variable *x* to *W*.
- panel_item* `W.pstyle_item(string s, point_style& x, void(*F)(int), const char * hlp = 0)`
 as above with action function *F*.
- panel_item* `W.pstyle_item(string s, point_style& x, const window_handler& obj, const char * hlp = 0)`
 as above with handler object *obj*.
- panel_item* `W.lstyle_item(string s, line_style& x, const char * hlp = 0)`
 adds a line style item with label *s* and variable *x* to *W*.
- panel_item* `W.lstyle_item(string s, line_style& x, void(*F)(int), const char * hlp = 0)`
 as above with action function *F*.
- panel_item* `W.lstyle_item(string s, line_style& x, const window_handler& obj, const char * hlp = 0)`
 as above with handler object *obj*.
- panel_item* `W.lwidth_item(string s, int& x, const char * hlp = 0)`
 adds a line width item with label *s* and variable *x* to *W*.
- panel_item* `W.lwidth_item(string s, int& x, void(*F)(int), const char * hlp = 0)`
 as above with action function *F*.
- panel_item* `W.lwidth_item(string s, int& x, const window_handler& obj, const char * hlp = 0)`
 as above with handler object *obj*.

3.9.3 Integer Choice Items

- panel_item* `W.int_item(string s, int& x, int l, int h, int step, const char * hlp = 0)`
 adds an integer choice item with label *s*, variable *x*, range *l*, ..., *h*, and step size *step* to *W*.
- panel_item* `W.int_item(string s, int& x, int l, int h, int step, void (*F)(int), const char * hlp = 0)`
 adds an integer choice item with label *s*, variable *x*, range *l*, ..., *h*, and step size *step* to *W*. Function *F(x)* is executed whenever the value of *x* is changed.
- panel_item* `W.int_item(string s, int& x, int l, int h, int step, const window_handler& obj, const char * hlp = 0)`
 as above with handler object *obj*.

- panel_item* $W.int_item(string\ s, int\&\ x, int\ l, int\ h, const\ char\ * hlp = 0)$
 adds an integer slider item with label s , variable x , and range l, \dots, h to W .
- panel_item* $W.int_item(string\ s, int\&\ x, int\ l, int\ h, void\ (*F)(int),$
 $const\ char\ * hlp = 0)$
 adds an integer slider item with label s , variable x , and range l, \dots, h to W . Function $F(x)$ is executed whenever the value of x has changed by moving the slider.
- panel_item* $W.int_item(string\ s, int\&\ x, int\ l, int\ h, const\ window_handler\&\ obj,$
 $const\ char\ * hlp = 0)$
 as above with handler object obj .

3.9.4 String Menu Items

- panel_item* $W.string_item(string\ s, string\&\ x, const\ list<string>\&\ L,$
 $const\ char\ * hlp = 0)$
 adds a string item with label s , variable x , and menu L to W .
- panel_item* $W.string_item(string\ s, string\&\ x, const\ list<string>\&\ L,$
 $const\ window_handler\&\ obj, const\ char\ * hlp = 0)$
 as above with handler object obj .
- panel_item* $W.string_item(string\ s, string\&\ x, const\ list<string>\&\ L, int\ sz,$
 $const\ char\ * hlp = 0)$
 menu L is displayed in a scroll box of height sz .
- panel_item* $W.string_item(string\ s, string\&\ x, const\ list<string>\&\ L, int\ sz,$
 $void\ (*F)(char*), const\ char\ * hlp = 0)$
 as above with action function F .
- panel_item* $W.string_item(string\ s, string\&\ x, const\ list<string>\&\ L, int\ sz,$
 $const\ window_handler\&\ obj, const\ char\ * hlp = 0)$
 as above with handler object obj .
- void* $W.set_menu(panel_item\ it, const\ list<string>\&\ L, int\ sz = 0)$
 replaces the menu of string menu item it by a menu for list L (table style if $sz = 0$ and scroll box with sz entries otherwise).

3.9.5 Choice Items

- panel_item* $W.choice_item(string\ s, int\&\ x, const\ list<string>\&\ L, void\ (*F)(int) = 0,$
 $const\ char\ * hlp = 0)$
 adds an integer item with label s , variable x , and choices from L to W .

- panel_item* `W.choice_item(string s, int& x, const list<string>& L, const window_handler& obj, const char * hlp = 0)`
as above with handler object *obj*.
- panel_item* `W.choice_item(string s, int& x, string s1, ..., string sk)`
adds an integer item with label *s*, variable *x*, and choices *s*₁, ..., *s*_{*k*} to *W* (*k* ≤ 8).
- panel_item* `W.choice_item(string s, int& x, int n, int w, int h, unsigned char **bm, const char * hlp = 0)`
adds an integer item with label *s*, variable *x*, and *n* bitmaps *bm*[0], ..., *bm*[*n* - 1] each of width *w* and height *h*.
- panel_item* `W.choice_item(string s, int& x, int n, int w, int h, unsigned char **bm, void (*F)(int), const char * hlp = 0)`
- panel_item* `W.choice_item(string s, int& x, int n, int w, int h, unsigned char **bm, const window_handler& obj, const char * hlp = 0)`
as above with handler object *obj*.

3.9.6 Multiple Choice Items

- panel_item* `W.choice_mult_item(string s, int& x, const list<string>& L, const char * hlp = 0)`
- panel_item* `W.choice_mult_item(string s, int& x, string s1, const char * hlp = 0)`
- panel_item* `W.choice_mult_item(string s, int& x, string s1, string s2, const char * hlp = 0)`
- panel_item* `W.choice_mult_item(string s, int& x, const list<string>& L, void (*F)(int), const char * hlp = 0)`
- panel_item* `W.choice_mult_item(string s, int& x, const list<string>& L, const window_handler& obj, const char * hlp = 0)`
- panel_item* `W.choice_mult_item(string s, int& x, int n, int w, int h, unsigned char **bm, const char * hlp = 0)`
- panel_item* `W.choice_mult_item(string s, int& x, int n, int w, int h, unsigned char **bm, void (*F)(int), const char * hlp = 0)`
- panel_item* `W.choice_mult_item(string s, int& x, int n, int w, int h, unsigned char **bm, const window_handler& obj, const char * hlp = 0)`

- int* `W.button(int w, int h, unsigned char * bm, string s, int n, void (*F)(int), const char * hlp = 0)`
 adds a button with bitmap *bm*, label *s*, number *n* and action function *F* to *W*. Function *F* is called with actual parameter *n* whenever the button is pressed.
- int* `W.button(int w, int h, unsigned char * bm, string s, int n, const window_handler& obj, const char * hlp = 0)`
- int* `W.button(char * pr1, char * pr2, string s, int n, void (*F)(int), const char * hlp = 0)`
 as above, but with pixrect *pr1* and *pr2*.
- int* `W.button(char * pr1, char * pr2, string s, int n, const window_handler& obj, const char * hlp = 0)`
- int* `W.button(string s, void (*F)(int), const char * hlp = 0)`
 adds a button with label *s*, number equal to its rank and action function *F* to *W*. Function *F* is called with the value of the button as argument whenever the button is pressed.
- int* `W.button(string s, const window_handler& obj, const char * hlp = 0)`
- int* `W.button(int w, int h, unsigned char * bm, string s, void (*F)(int), const char * hlp = 0)`
 adds a button with bitmap *bm*, label *s*, number equal to its rank and action function *F* to *W*. Function *F* is called with the value of the button as argument whenever the button is pressed.
- int* `W.button(int w, int h, unsigned char * bm, string s, const window_handler& obj, const char * hlp = 0)`
- int* `W.button(char * pr1, char * pr2, string s, void (*F)(int), const char * hlp = 0)`
 as above, but with pixrect *pr1* and *pr2*.
- int* `W.button(char * pr1, char * pr2, string s, const window_handler& obj, const char * hlp = 0)`
- int* `W.button(string s, int n, window& M, const char * hlp = 0)`
 adds a button with label *s*, number *n* and attached sub-window (menu) *M* to *W*. Window *M* is opened whenever the button is pressed.

<i>int</i>	<i>W.button(int w, int h, unsigned char * bm, string s, int n, window& M, const char * hlp = 0)</i>	adds a button with bitmap <i>bm</i> , label <i>s</i> , number <i>n</i> and attached sub-window (menu) <i>M</i> to <i>W</i> . Window <i>M</i> is opened whenever the button is pressed.
<i>int</i>	<i>W.button(char * pr1, char * pr2, string s, int n, window& M, const char * hlp = 0)</i>	as above, but with pixrect <i>pr1</i> and <i>pr2</i> .
<i>int</i>	<i>W.button(string s, window& M, const char * hlp = 0)</i>	adds a button with label <i>s</i> and attached sub-window <i>M</i> to <i>W</i> . The number returned by <i>read_mouse</i> is the number of the button selected in sub-window <i>M</i> .
<i>int</i>	<i>W.button(int w, int h, unsigned char * bm, string s, window& M, const char * hlp = 0)</i>	adds a button with bitmap <i>bm</i> , label <i>s</i> and attached sub-window <i>M</i> to <i>W</i> . The number returned by <i>read_mouse</i> is the number of the button selected in sub-window <i>M</i> .
<i>int</i>	<i>W.button(char * pr1, char * pr2, string s, window& M, const char * hlp = 0)</i>	as above, but with pixrect <i>pr1</i> and <i>pr2</i> .
<i>void</i>	<i>W.make_menu_bar()</i>	inserts a menu bar at the top of the panel section that contains all previously added menu buttons (buttons with a subwindow attached).
<i>window*</i>	<i>window::get_callwindow()</i>	A static function that can be called in action functions attached to panel items or buttons to retrieve a pointer to the window containing the corresponding item or button.
<i>panel_item</i>	<i>window::get_callitem()</i>	A static function that can be called in action functions attached to panel items to retrieve the corresponding item.
<i>int</i>	<i>window::get_callbutton()</i>	A static function that can be called in action functions attached to panel buttons to retrieve the number of the corresponding button.

3.9.8. Manipulating Panel Items and Buttons

Disabling and Enabling Items or buttons

<i>void</i>	<i>W.disable_item(panel_item it)</i>	disables panel item <i>it</i> .
<i>void</i>	<i>W.enable_item(panel_item it)</i>	enables panel item <i>it</i> .
<i>bool</i>	<i>W.is_enabled(panel_item it)</i>	tests whether item <i>it</i> is enabled or not.
<i>void</i>	<i>W.disable_button(int b)</i>	disables button <i>b</i> .
<i>void</i>	<i>W.enable_button(int b)</i>	enables button <i>b</i> .
<i>void</i>	<i>W.disable_buttons()</i>	disables all buttons.
<i>void</i>	<i>W.enable_buttons()</i>	enables all buttons.
<i>bool</i>	<i>W.is_enabled(int b)</i>	tests whether button <i>b</i> is enabled or not.
<i>void</i>	<i>W.disable_panel(bool disable_every_item = true)</i>	disables the entire panel section of <i>W</i> .
<i>void</i>	<i>W.enable_panel()</i>	enables the entire panel section of <i>W</i> .

Accessing and Updating Item Data

<i>void</i>	<i>W.set_text(panel_item it, string s)</i>	replaces the text of text item <i>it</i> by <i>s</i> .
<i>panel_item</i>	<i>W.get_item(string s)</i>	returns the item with label <i>s</i> and <i>NULL</i> if no such item exists in <i>W</i> .
<i>int</i>	<i>W.get_button(string s)</i>	returns the button with label <i>s</i> and -1 if no such button exists in <i>W</i> .
<i>string</i>	<i>W.get_button_label(int but)</i>	returns the label of button <i>but</i> .
<i>void</i>	<i>W.set_button_label(int but, string s)</i>	sets the label of button <i>but</i> to <i>s</i> .
<i>void</i>	<i>W.set_button_pixrects(int but, char * pr1, char * pr2)</i>	sets the pixrects of button <i>but</i> to <i>pr1</i> and <i>pr2</i> .
<i>window*</i>	<i>W.get_window(int but)</i>	returns a pointer to the subwindow attached to button <i>but</i> (<i>NULL</i> if <i>but</i> has no subwindow)
<i>window*</i>	<i>W.set_window(int but, window * M)</i>	associates subwindow (menu) <i>*M</i> with button <i>but</i> . Returns a pointer to the window previously attached to <i>but</i> .

18.3 Panels (`panel`)

1. Definition

Panels are windows consisting of a panel section only (cf. section 18.2). They are used for displaying text messages and updating the values of variables.

```
#include < LEDA/graphics/panel.h >
```

2. Creation

```
panel P;                    creates an empty panel P.
```

```
panel P(string s);        creates an empty panel P with header s.
```

```
panel P(int w, int h);                    creates an empty panel P of width w and height h.
```

```
panel P(int w, int h, string s);        creates an empty panel P of width w and height h with header s.
```

3. Operations

All window operations for displaying, reading, closing and adding panel items are available (see section 18.2). There are two additional operations for opening and reading panels.

```
int P.open(int x = window::center, int y = window::center)  
                                          P.display(x, y) + P.read_mouse( ) + P.close( ).
```

```
int P.open(window& W, int x = window::center, int y = window::center)  
                                          P.display(W, x, y) + P.read_mouse( ) + P.close( ).
```

18.4 Menues (menu)

1. Definition

Menues are special panels consisting only of a vertical list of buttons.

```
#include < LEDA/graphics/menu.h >
```

2. Creation

menu *M*; creates an empty menu *M*.

3. Operations

int *M.button(string s, int n)* adds a button with label *s* and number *n* to *M*.

int *M.button(string s)* adds a new button to *M* with label *s* and number equal to its position in the list of all buttons (starting with 0).

int *M.button(string s, int n, void (*F)(int))*
 adds a button with label *s*, number *n* and action function *F* to *M*. Function *F* is called with actual parameter *n* whenever the button is pressed.

int *M.button(string s, int n, const window_handler& obj)*
 as above with handler object *obj*.

int *M.button(string s, void (*F)(int))*
 adds a button with label *s*, number equal to its rank and action function *F* to *M*. Function *F* is called with the number of the button as argument whenever the button is pressed.

int *M.button(string s, const window_handler& obj)*
 as above with handler object *obj*.

int *M.button(string s, int n, window& W)*
 adds a button with label *s*, number *n*, and attached window *W* to *M*. Whenever the button is pressed *W* is opened.

int *M.button(string s, window& W)*
 adds a button with label *s* and attached window *W* to *M*. Whenever the button is pressed *W* is opened and *W.read_mouse()* is returned.

void *M.separator()* inserts a separator (horizontal line) at the current position.

int *M*.open(*window& W*, *int x*, *int y*)

open and read menu *M* at position (x, y) in window *W*.

18.5 Postscript Files (*ps_file*)

1. Definition

The data type *ps_file* is a graphical input/output interface for the familiar LEDA drawing operations of two-dimensional geometry. Unlike the data type *window*, the output produced by a *ps_file* object is *permanent*, i.e., it is not lost after exiting the C++-program as it is saved in an output file.

An instance of type *ps_file* is (as far as the user takes notice of it) an ordinary ASCII file that contains the source code of the graphics output in the PostScript description language. After running the C++-program, the file is created in the user's current working directory and can later be handled like any other PostScript file, i.e., it may be viewed, printed etc.

Of course, features like a panel section (as in *window* type instances) don't make sense for a representation that is not supposed to be displayed on the screen and interactively worked with by the user. Therefore, only drawing operations are applicable to a *ps_file* instance.

ps_file was implemented by

Thomas Wahl
Lehrstuhl für Informatik I
Universität Würzburg

The complete user manual can be found in LEDAROOT/Manual/contrib.

```
#include < LEDA/graphics/ps_file.h >
```

18.6 Graph Windows (GraphWin)

1. Definition

GraphWin combines the two types *graph* and *window* and forms a bridge between the graph data types and algorithms and the graphics interface of LEDA. *GraphWin* can easily be used in LEDA programs for constructing, displaying and manipulating graphs and for animating and debugging graph algorithms.

- The user interface of GraphWin is simple and intuitive. When clicking a mouse button inside the drawing area a corresponding default action is performed that can be redefined by users. With the initial default settings, the left mouse button is used for creating and moving objects, the middle button for selecting objects, and the right button for destroying objects. A number of menus at the top of the window give access to graph generators, modifiers, basic algorithms, embeddings, setup panels, and file input and output.
- Graphwin can display and manipulate the data associated with the nodes and edges of LEDA's parameterized graph type $GRAPH < vtype, etype >$. When a GraphWin is opened for such a graph the associated node and edge labels of type *vtype* and *etype* can be displayed and edited.
- Most of the actions of GraphWin can be customized by modifying or extending the menus of the main window or by defining call-back functions. So the user can define what happens if a node or edge is created, selected, moved, or deleted.
- Graphwin offers a collection of graph generators, modifiers and tests. The generators include functions for constructing random, planar, complete, bipartite, grid graph, connected graph, biconnected, graphs ...

There are also methods for modifying existing graphs (e.g. by removing or adding a certain set of edges) to fit in one of these categories and for testing whether a given graph is planar, connected, bipartite ...

- The standard menu includes a choice of fundamental graph algorithms and basic embedding algorithms.

For every node and edge of the graph GraphWin maintains a set of parameters.

With every node is associated the following list of parameters. Note that for every parameter there are corresponding set and get operations (`gw.set_param()` and `gw.get_param()`) where `param` has to be replaced by the corresponding parameter name.

position: the position of the node (type *point*),

shape: the shape of the node (type *gw_node_shape*),
color: the color of the interior of the node (type *color*),
border_color: the color of the node's border (type *color*),
label_color: the color of the node's label (type *color*),
pixmap: the pixmap used to fill the interior of the node (*char**),
width: the width of the node in pixels (*int*),
height: the height of the node in pixels (*int*),
radius1: the horizontal radius in real world coordinates (*double*)
radius2: the vertical radius in real world coordinates (*double*),
border_width: the width of the border in pixels (*int*),
label_type: the type of the node's label (type *gw_label_type*),
user_label: the user label of the node (type *string*), and
label_pos: the position of the label (type *gw_position*).

With every edge is associated the following list of parameters

color: the color of the edge (type *color*),
label_color: the color of the edge label (type *color*),
shape: the shape of the edge (type *gw_edge_shape*),
style: the style of the edge (type *gw_edge_style*),
direction: the direction of the edge (type *gw_edge_dir*),
width: the width of the edge in pixels (type *int*),
label_type: the label type of the edge (type *gw_label_type*),
user_label: the user label of the edge (type *string*),
label_pos: the position of the edge's label (type *gw_position*),
bends: the list of edge bends (type *list<point>*),
source_anchor: the source anchor of the edge (type *point*), and
target_anchor: the target anchor of the edge (type *point*).

The corresponding types are:

```
gw_node_shape = { circle_node, ellipse_node, square_node, rectangle_node }
gw_edge_shape = { poly_edge, circle_edge, bezier_edge, spline_edge }
```

```
gw_position = { central_pos, northwest_pos, north_pos,
               northeast_pos, east_pos, southeast_pos,
               south_pos, southwest_pos, west_pos }
```

```
gw_label_type = { no_label, user_label, data_label, index_label }
```

```
gw_edge_style = { solid_edge, dashed_edge, dotted_edge, dashed_dotted_edge }
```

```
gw_edge_dir   = { undirected_edge, directed_edge, bidirected_edge, rdirected_edge };
```

```
#include < LEDA/graphics/graphwin.h >
```

2. Creation

```
GraphWin gw(graph& G, int w, int h, const char * win_label = "");
```

creates a graph window for graph G with a display window of size w pixels \times h pixels. If win_label is not empty it is used as the frame label of the window, otherwise, a default frame label is used.

```
GraphWin gw(graph& G, const char * win_label = "");
```

creates a graph window for graph G with a display window of default size and frame label win_label .

```
GraphWin gw(int w, int h, const char * win_label = "");
```

creates a graph window for a new empty graph with a display window of size w pixels \times h pixels, and frame label win_label .

```
GraphWin gw(const char * win_label = "");
```

creates a graph window for a new empty graph with a display window of default size and frame label win_label .

```
GraphWin gw(window& W);
```

as above, but W is used as display window.

```
GraphWin gw(graph& G, window& W);
```

as above, but makes G the graph of gw .

3. Operations

a) Window Operations

<i>void</i>	<i>gw.display(int x, int y)</i>	displays gw with upper left corner at (x, y) . The predefined constant <i>window::center</i> can be used to center the window horizontally (if passed as x) or vertically (if passed as y).
<i>void</i>	<i>gw.display()</i>	displays gw at default position.
<i>bool</i>	<i>gw.edit()</i>	enters the edit mode of <i>GraphWin</i> that allows to change the graph interactively by operations associated with certain mouse events or by choosing operations from the windows menu bar (see section about edit-mode) for a description of the available commands and operations). Edit mode is terminated by either pressing the <i>done</i> button or by selecting <i>exit</i> from the file menu. In the first case the result of the edit operation is <i>true</i> and in the latter case the result is <i>false</i> .
<i>bool</i>	<i>gw.open(int x, int y)</i>	displays the window at position (x, y) , enters edit mode and return the corresponding result.
<i>bool</i>	<i>gw.open()</i>	as above, but displays the window at default position.
<i>void</i>	<i>gw.close()</i>	closes the window.
<i>void</i>	<i>gw.message(const char * msg)</i>	displays the message <i>msg</i> at the top of the window.
<i>string</i>	<i>gw.get_message()</i>	returns the current message string.
<i>void</i>	<i>gw.del_message()</i>	deletes a previously written message.
<i>double</i>	<i>gw.get_xmin()</i>	returns the minimal x-coordinate of the window.
<i>double</i>	<i>gw.get_ymin()</i>	returns the minimal y-coordinate of the window.
<i>double</i>	<i>gw.get_xmax()</i>	returns the maximal x-coordinate of the window.
<i>double</i>	<i>gw.get_ymax()</i>	returns the maximal y-coordinate of the window.
<i>void</i>	<i>gw.win_init(double xmin, double xmax, double ymin)</i>	sets the coordinates of the window to $(xmin, xmax, ymin)$.
<i>void</i>	<i>gw.redraw()</i>	redraws the graph. If the <i>flush</i> parameter of <i>gw</i> is set to false (see <i>set_flush</i>) this operation can be used to display the current state of the graph after a number of update operations.

<i>void</i>	<i>gw.set_frame_label(const char * label)</i>	makes <i>label</i> the frame label of the window.
<i>int</i>	<i>gw.open_panel(panel& P)</i>	displays panel <i>P</i> centered on the drawing area of <i>gw</i> , disables the menu bar of <i>gw</i> and returns the result of <i>P.open()</i> .
<i>window&</i>	<i>gw.get_window()</i>	returns a reference to the window of <i>gw</i> .
<i>void</i>	<i>gw.finish_menu_bar()</i>	this operation has to called before additional buttons are added to the panel section of <i>gw.get_window()</i> .

b) Graph Operations

<i>node</i>	<i>gw.new_node(const point& p)</i>	adds a new node at position <i>p</i> to <i>gw</i> .
<i>void</i>	<i>gw.delnode(node v)</i>	deletes <i>v</i> and all edges incident to <i>v</i> from <i>gw</i> .
<i>edge</i>	<i>gw.new_edge(node v, node w)</i>	adds a new edge (<i>v, w</i>) to <i>gw</i> .
<i>edge</i>	<i>gw.new_edge(node v, node w, const list<point>& P)</i>	adds a new edge (<i>v, w</i>) with bend sequence <i>P</i> to <i>gw</i> .
<i>void</i>	<i>gw.delEdge(edge e)</i>	deletes edge <i>e</i> from <i>gw</i> .
<i>void</i>	<i>gw.clear_graph()</i>	deletes all nodes and edges.
<i>graph&</i>	<i>gw.get_graph()</i>	returns a reference of the graph of <i>gw</i> .
<i>void</i>	<i>gw.update_graph()</i>	this operation has to be called after any update operation that has been performed directly (not by GraphWin) on the underlying graph, e.g., deleting or inserting nodes or edges.

c) Node Parameters

Node parameters can be retrieved or changed by a collection of *get-* and *set-* operations. We use *param_type* for the type and *param* for the value of the corresponding parameter.

Individual Parameters

<i>param_type</i>	<i>gw.get_param(node v)</i>	returns the value of parameter <i>param</i> for node <i>v</i> .
-------------------	-----------------------------	---

- param_type* *gw.set_param*(*node v*, *param_type x*)
sets the value of parameter *param* for node *v* to *x*. and returns its previous value.
- void* *gw.set_param*(*list<node>& L*, *param_type x*)
sets the value of parameter *param* for all nodes in *L* to *x*.

Default Parameters

- param_type* *gw.get_node_param*() returns the current default value of parameter *param*.
- param_type* *gw.set_node_param*(*param_type x*, *bool apply = true*)
sets the default value of parameter *param* to *x*. and returns its previous value. If *apply == true* the parameter is changed for all existing nodes as well.

d) Edge Parameters

Individual Parameters

- param_type* *gw.get_param*(*edge e*) returns the value of parameter *param* for edge *e*.
- param_type* *gw.set_param*(*edge e*, *param_type x*)
sets the value of parameter *param* for edge *e* to *x*. and returns its previous value.
- void* *gw.set_param*(*list<edge>& L*, *param_type x*)
sets the value of parameter *param* for all edges in *L* to *x*.

Default Parameters

- param_type* *gw.get_edge_param*() returns the current default value of parameter *param*.
- param_type* *gw.set_edge_param*(*param_type x*, *bool apply = true*)
sets the default value of parameter *param* to *x*. and returns its previous value. If *apply == true* the parameter is changed for all existing edges as well.

e) Global Options

- int* *gw.set_gen_nodes*(*int n*) sets the default number of nodes *n* for all graph generator dialog panels.

<i>int</i>	<i>gw.set_gen_edges(int m)</i>	sets the default number of edges <i>m</i> for all graph generator dialog panels.
<i>int</i>	<i>gw.set_edge_distance(int d)</i>	sets the distance of multi-edges to <i>d</i> pixels.
<i>grid_style</i>	<i>gw.set_grid_style(grid_style s)</i>	sets the grid style to <i>s</i> .
<i>int</i>	<i>gw.set_grid_dist(int d)</i>	sets the grid distance to <i>d</i> .
<i>int</i>	<i>gw.set_grid_size(int n)</i>	sets the grid distance such that <i>n</i> vertical grid lines lie inside the drawin area.
<i>bool</i>	<i>gw.set_show_status(bool b)</i>	display a status window (<i>b=true</i>) or not (<i>b=false</i>).
<i>color</i>	<i>gw.set_bg_color(color c)</i>	sets the window background color to <i>c</i> .
<i>char*</i>	<i>gw.set_bg_pixmap(char * pr, double xorig = 0, double yorig = 0)</i>	sets the window background pixmap to <i>pr</i> and the tiling origin to (<i>xorig, yorig</i>).
<i>void</i>	<i>gw.set_bg_xpm(const char **xpm_data)</i>	sets the window background pixmap to the pixmap defined by <i>xpm_data</i> .
<i>void</i>	<i>gw.set_bg_redraw(void (*f)(window*, double, double, double, double))</i>	sets the window background redraw function to <i>f</i> .
<i>void</i>	<i>gw.set_node_label_font(gw_font_type t, int sz)</i>	sets the node label font type and size. Possible types are <i>roman_font</i> , <i>bold_font</i> , <i>italic_font</i> , and <i>fixed_font</i> .
<i>void</i>	<i>gw.set_node_label_font(string fn)</i>	sets the node label font to the font with name <i>fn</i> .
<i>void</i>	<i>gw.set_edge_label_font(gw_font_type t, int sz)</i>	sets the edge label font type and size. <i>roman_font</i> , <i>bold_font</i> , <i>italic_font</i> , and <i>fixed_font</i> .
<i>void</i>	<i>gw.set_edge_label_font(string fn)</i>	sets the edge label font to the font with name <i>fn</i> .
<i>string</i>	<i>gw.set_node_index_format(string s)</i>	sets the node index format string to <i>s</i> .

<i>string</i>	<i>gw.setEdgeIndexFormat(string s)</i>	sets the edge index format string <i>s</i> .
<i>bool</i>	<i>gw.setEdgeBorder(bool b)</i>	sets the edge border flag to <i>b</i> .
<i>bool</i>	<i>gw.enableLabelBox(bool b)</i>	enables/disables drawing of blue label boxes. Label boxes are enabled per default.

Animation and Zooming

<i>int</i>	<i>gw.setAnimationSteps(int s)</i>	move a node in <i>s</i> steps to its new position.
<i>bool</i>	<i>gw.setFlush(bool b)</i>	show operations on <i>gw</i> instantly (<i>b=true</i>) or not (<i>b=false</i>).
<i>double</i>	<i>gw.setZoomFactor(double f)</i>	sets the zoom factor to <i>f</i> used when zooming from menu.
<i>bool</i>	<i>gw.setZoomObjects(bool b)</i>	resize nodes and edges when zooming (<i>b==true</i>) or not (<i>b==false</i>).
<i>bool</i>	<i>gw.setZoomLabels(bool b)</i>	resize labels when zooming (<i>b==true</i>) or not (<i>b==false</i>).

f) Node and Edge Selections

<i>void</i>	<i>gw.select(node v)</i>	adds <i>v</i> to the list of selected nodes.
<i>void</i>	<i>gw.selectAllNodes()</i>	selects all nodes.
<i>void</i>	<i>gw.deselect(node v)</i>	deletes <i>v</i> from the list of selected nodes.
<i>void</i>	<i>gw.deselectAllNodes()</i>	clears the current node selection.
<i>bool</i>	<i>gw.isSelected(node v)</i>	returns <i>true</i> if <i>v</i> is selected and <i>false</i> otherwise.
<i>const list<node>&</i>	<i>gw.getSelectedNodes()</i>	returns the current node selection.
<i>void</i>	<i>gw.select(edge e)</i>	adds <i>e</i> to the list of selected edges.
<i>void</i>	<i>gw.selectAllEdges()</i>	selects all edges.

void gw.deselect(edge e) deletes e from the list of selected edges.

void gw.deselect_allEdges() clears the current node selection.

bool gw.is_selected(edge e) returns *true* if e is selected and *false* otherwise.

const list<edge>& gw.get_selectedEdges()
returns the current edge selection.

void gw.deselect_all() clears node and edge selections.

g) Layout Operations

void gw.set_position(const node_array<point>& pos)
for every node v of G the position of v is set to $pos[v]$.

*void gw.set_position(const node_array<double>& x,
const node_array<double>& y)*
for every node v of G the position of v is set to $(x[v], y[v])$.

void gw.get_position(node_array<point>& pos)
for every node v of G the position of v is assigned to $pos[v]$.

*void gw.set_layout(const node_array<point>& pos,
const node_array<double>& r1,
const node_array<double>& r2, const edge_array<list<point>
>& bends, const edge_array<point>& sanch,
const edge_array<point>& tanch)*
for every node v the position is set to $pos[v]$ and $radius_i$ is set to $r_i[v]$. For every edge e the list of bends is set to $bends[e]$ and source (target) anchor is set to $sanch[e]$ ($tanch[e]$).

*void gw.set_layout(const node_array<point>& pos, const edge_array<list<point>
>& bends, bool reset_anchors = true)*
for every node v the position is set to $pos[v]$ and for every edge e the list of bends is set to $bends[e]$.

void gw.set_layout(const node_array<point>& pos)
for every node v the position is set to $pos[v]$ and for every edge e the list of bends is made empty.

void gw.set_layout(const node_array<double>& x, const node_array<double>& y)
for every node v the position is set to $(x[v], y[v])$ and for every edge e the list of bends is made empty.

void *gw.set_layout()* same as *gw.remove_bends()*.

void *gw.transform_layout*(*node_array<double>& xpos*,
 node_array<double>& ypos, *edge_array<list<double>*
 >& xbends, *edge_array<list<double>* *>& ybends*,
 double dx, *double dy*, *double fx*, *double fy*)
 transforms the layout given by *xpos*, *ypos*, *xbends*,
 and *ybends* by transforming every node position or
 edge bend (x, y) to $(dx + fx * x, dy + fy * y)$. The
 actual layout of the current graph is not changed
 by this operation.

void *gw.transform_layout*(*node_array<double>& xpos*,
 node_array<double>& ypos,
 node_array<double>& xrad,
 node_array<double>& yrad, *edge_array<list<double>*
 >& xbends, *edge_array<list<double>* *>& ybends*,
 double dx, *double dy*, *double fx*, *double fy*)
 as above, in addition the horizontal and vertical
 radius of every node (given in the arrays *xrad* and
 yrad) are enlarged by a factor of *fx* and *fy*, re-
 spectively.

void *gw.fill_win_params*(*double wx0*, *double wy0*, *double wx1*, *double wy1*,
 double x0, *double y0*, *double x1*, *double y1*,
 double& dx, *double& dy*, *double& fx*, *double& fy*)
 computes parameters *dx*, *dy*, *fx*, and *fy* for trans-
 forming rectangle $x0, y0, x1, y1$ into (window) rect-
 angle $wx0, wy0, wx1, wy1$.

void *gw.fill_win_params*(*double wx0*, *double wy0*, *double wx1*, *double wy1*,
 node_array<double>& xpos, *node_array<double>& ypos*,
 edge_array<list<double> *>& xbends*,
 edge_array<list<double> *>& ybends*, *double& dx*,
 double& dy, *double& fx*, *double& fy*)
 computes parameters *dx*, *dy*, *fx*, and *fy* for trans-
 forming the layout given *xpos*, *ypos*, *xbends*, *ybends*
 to fill the (window) rectangle $wx0, wy0, wx1, wy1$.

- void* `gw.fill_win_params(double wx0, double wy0, double wx1, double wy1, node_array<double>& xpos, node_array<double>& ypos, node_array<double>& xrad, node_array<double>& yrad, edge_array<list<double>>& xbends, edge_array<list<double>>& ybends, double& dx, double& dy, double& fx, double& fy)`
 computes parameters dx , dy , fx , and fy for transforming the layout given $xpos, ypos, xbends, ybends, xrad, yrad$ to fill the (window) rectangle $wx0, wy0, wx1, wy1$.
- void* `gw.place_into_box(double x0, double y0, double x1, double y1)`
 moves and stretches the graph to fill the given rectangular box $(x0, y0, x1, y1)$ by appropriate scaling and translating operations.
- void* `gw.place_into_win()` moves and stretches the graph to fill the entire window by appropriate scaling and translating operations.
- void* `gw.adjust_coords_to_box(node_array<double>& xpos, node_array<double>& ypos, edge_array<list<double>>& xbends, edge_array<list<double>>& ybends, double x0, double y0, double x1, double y1)`
 transforms the layout given by $xpos, ypos, xbends$, and $ybends$ in such way as a call of `place_into_box(x0, y0, x1, y1)` would do. However, the actual layout of the current graph is not changed by this operation.
- void* `gw.adjust_coords_to_box(node_array<double>& xpos, node_array<double>& ypos, double x0, double y0, double x1, double y1)`
 transforms the layout given by $xpos, ypos$ in such way as a call of `place_into_box(x0, y0, x1, y1)` would do ignoring any edge bends. The actual layout of the current graph is not changed by this operation.
- void* `gw.adjust_coords_to_win(node_array<double>& xpos, node_array<double>& ypos, edge_array<list<double>>& xbends, edge_array<list<double>>& ybends)`
 same as `adjust_coords_to_box(xpos, ypos, xbends, ybends, wx0, wy0, wx1, wy1)` for the current window rectangle $(wx0, wy0, wx1, wy1)$.

<i>void</i>	<i>gw.adjust_coords_to_win</i> (<i>node_array<double>& xpos</i> , <i>node_array<double>& ypos</i>)	same as <i>adjust_coords_to_box</i> (<i>xpos</i> , <i>ypos</i> , <i>wx0</i> , <i>wy0</i> , <i>wx1</i> , <i>wy1</i>) for the current window rectangle (<i>wx0</i> , <i>wy0</i> , <i>wx1</i> , <i>wy1</i>).
<i>void</i>	<i>gw.remove_bends</i> (<i>edge e</i>)	removes all bends from edge <i>e</i> .
<i>void</i>	<i>gw.remove_bends</i> ()	removes the bends of all edges of the graph.
<i>void</i>	<i>gw.reset_edge_anchors</i> ()	resets all edge anchor positions to (0, 0).
<i>int</i>	<i>gw.load_layout</i> (<i>istream& istr</i>)	read layout from stream <i>istr</i> .
<i>bool</i>	<i>gw.save_layout</i> (<i>ostream& ostr</i>)	save layout to stream <i>ostr</i> .
<i>bool</i>	<i>gw.save_layout</i> (<i>string fname</i> , <i>bool ask_override = false</i>)	save layout to file <i>fname</i> .

h) Zooming

<i>void</i>	<i>gw.zoom</i> (<i>double f</i>)	zooms the window by factor <i>f</i> .
<i>void</i>	<i>gw.zoom_area</i> (<i>double x0</i> , <i>double y0</i> , <i>double x1</i> , <i>double y1</i>)	performs a zoom operation for the rectangular area with current coordinates (<i>x0</i> , <i>y0</i> , <i>x1</i> , <i>y1</i>).
<i>void</i>	<i>gw.zoom_graph</i> ()	performs a zoom operation, such that the graph fills the entire window.
<i>void</i>	<i>gw.unzoom</i> ()	undoes last zoom operation.

i) Operations in Edit-mode

Before entering edit mode ...

<i>gw_action</i>	<i>gw.set_action</i> (<i>long mask</i> , <i>gw_action func</i>)	sets action associated with condition <i>mask</i> to <i>func</i> and returns previous action for this condition. Here <i>gw_action</i> is the type <i>void (*func)(GraphWin&, const point&)</i> . For <i>func = NULL</i> the corresponding action is deleted.
<i>gw_action</i>	<i>gw.get_action</i> (<i>long mask</i>)	returns the action associated with condition <i>mask</i> .

- void* `gw.reset_actions()` resets all actions to their defaults.
- void* `gw.clear_actions()` deletes all actions.
- void* `gw.add_node_menu(string label, gw_action func)`
appends action function *func* with label *label* to the context menu for nodes (opened by clicking with the right mouse button on a node).
- void* `gw.add_edge_menu(string label, gw_action func)`
appends action function *func* with label *label* to the context menu for edges (opened by clicking with the right mouse button on an edge).
- void* `gw.set_new_node_handler(bool (*f)(GraphWin& , const point&))`
f(gw, p) is called every time before a node is to be created at position *p*.
- void* `gw.set_new_node_handler(void (*f)(GraphWin& , node) = NULL)`
f(gw, v) is called after node *v* has been created.
- void* `gw.set_new_edge_handler(bool (*f)(GraphWin& , node, node))`
f(gw, v, w) is called before the edge (*v, w*) is to be created.
- void* `gw.set_new_edge_handler(void (*f)(GraphWin& , edge) = NULL)`
f(gw, e) is called after the edge *e* has been created.
- void* `gw.set_start_move_node_handler(bool (*f)(GraphWin& , node) = NULL)`
f(gw, v) is called before node *v* is to be moved.
- void* `gw.set_move_node_handler(void (*f)(GraphWin& , node) = NULL)`
f(gw, v) is called every time node *v* reaches a new position during a move operation.
- void* `gw.set_end_move_node_handler(void (*f)(GraphWin& , node))`
f(gw, v) is called after node *v* has been moved.
- void* `gw.set_delnode_handler(bool (*f)(GraphWin& , node))`
f(gw, v) is called before the node *v* is to be deleted.
- void* `gw.set_delnode_handler(void (*f)(GraphWin&) = NULL)`
f(gw) is called every time after a node was deleted.
- void* `gw.set_deledge_handler(bool (*f)(GraphWin& , edge))`
f(gw, e) is called before the edge *e* is to be deleted.

<i>int</i>	<i>gw.add_simple_call(void (*func)(GraphWin&), string label, int menu_id, int bm_w, int bm_h, unsigned char * bm_bits)</i> ...	
<i>int</i>	<i>gw.add_member_call(void (GraphWin:: * func)(), string label, int menu_id = 0, char * pmap = 0)</i> ...	
<i>int</i>	<i>gw.add_member_call(void (GraphWin:: * func)(), string label, int menu_id, int bm_w, int bm_h, unsigned char * bm_bits)</i> ...	
<i>void</i>	<i>gw.add_separator(int menu_id)</i> ...	
<i>void</i>	<i>gw.display_help_text(string fname)</i> displays the help text contained in <i>name.help</i> . The file <i>name.help</i> must exist either in the current working directory or in <i>\$LEDAROOT/incl/Help</i> .	
<i>void</i>	<i>gw.add_help_text(string name)</i> adds the help text contained in <i>name.help</i> with label <i>name</i> to the help menu of the main window. The file <i>name.help</i> must exist either in the current working directory or in <i>\$LEDAROOT/incl/Help</i> . Note that this operation must be called before <i>gw.display()</i> .	
<i>int</i>	<i>gw.get_menu(string label)</i> returns the number of the submenu with label <i>label</i> or -1 if no such menu exists.	
<i>void</i>	<i>gw.enable_call(int id)</i> enable call with id <i>id</i> .	
<i>void</i>	<i>gw.disable_call(int id)</i> disable call with id <i>id</i> .	
<i>bool</i>	<i>gw.is_call_enabled(int id)</i> check if call with <i>id</i> is enabled.	
<i>void</i>	<i>gw.enable_calls()</i> ...	
<i>void</i>	<i>gw.disable_calls()</i> ...	

k) Input/Output

<i>int</i>	<i>gw.read_gw(istream& in)</i> reads graph in <i>gw</i> format from stream <i>in</i> .
<i>int</i>	<i>gw.read_gw(string fname)</i> reads graph in <i>gw</i> format from file <i>fname</i> .

- bool* *gw.save_gw(ostream& out)*
writes graph in *gw* format to output stream *out*.
- bool* *gw.save_gw(string fname, bool ask_override = false)*
saves graph in *gw* format to file *fname*.
- int* *gw.read_gml(istream& in)*
reads graph in GML format from stream *in*.
- int* *gw.read_gmlstring(string s)*
reads graph in GML format from string *s*.
- int* *gw.read_gml(string fname, bool ask_override = false)*
reads graph in GML format from file *fname*. Returns 1 if *fname* cannot be opened, 2 if a parser error occurs, and 0 on success.
- bool* *gw.save_gml(ostream& out)*
writes graph in GML format to output stream *out*.
- bool* *gw.save_gml(string fname, bool ask_override = false)*
saves graph to file *fname* in GML format.
- bool* *gw.save_ps(string fname, bool ask_override = false)*
saves a postscript representation of the graph to *fname*.
- bool* *gw.save_svg(string fname, bool ask_override = false)*
saves a SVG representation of the graph to *fname*.
- bool* *gw.save_latex(string fname, bool ask_override = false)*
saves a postscript/latex representation of the graph to *fname*.
- bool* *gw.save_wmf(string fname, bool ask_override = false)*
saves a windows metafile representation of the graph to *fname*.
- bool* *gw.unsaved_changes()* returns true if the graph has been changed after the last save (*gw* or *gml*) operation.
- bool* *gw.save_defaults(string fname)*
saves the default attributes of nodes and edges to file *fname*.
- bool* *gw.read_defaults(string fname)*
reads the default attributes of nodes and edges from file *fname*.

1) Miscellaneous

<i>void</i>	<i>gw.set_window(window& W)</i>	makes <i>W</i> the window of <i>gw</i> .
<i>void</i>	<i>gw.set_graph(graph& G)</i>	makes <i>G</i> the graph of <i>gw</i> .
<i>void</i>	<i>gw.undo_clear()</i>	empties the undo and redo stacks.
<i>bool</i>	<i>gw.wait()</i>	waits until the done button is pressed (<i>true</i> returned) or exit is selected from the file menu (<i>false</i> returned).
<i>bool</i>	<i>gw.wait(const char * msg)</i>	displays <i>msg</i> and waits until the done button is pressed (<i>true</i> returned) or exit is selected from the file menu (<i>false</i> returned).
<i>bool</i>	<i>gw.wait(float sec, const char * msg = "")</i>	as above but waits no longer than <i>sec</i> seconds returns ?? if neither button was pressed within this time interval.
<i>void</i>	<i>gw.acknowledge(string s)</i>	displays string <i>s</i> and asks for acknowledgement.
<i>node</i>	<i>gw.ask_node()</i>	asks the user to select a node with the left mouse button. If a node is selected it is returned otherwise nil is returned.
<i>edge</i>	<i>gw.ask_edge()</i>	asks the user to select an edge with the left mouse button. If an edge is selected it is returned otherwise nil is returned.
<i>bool</i>	<i>gw.define_area(double& x0, double& y0, double& x1, double& y1, const char * msg = "")</i>	displays message <i>msg</i> and returns the coordinates of a rectangular area defined by clicking and dragging the mouse.
<i>list<node></i>	<i>gw.get_nodes_in_area(double x0, double y0, double x1, double y1)</i>	returns the list of nodes intersecting the rectangular area (<i>x0, y0, x1, y1</i>).
<i>list<edge></i>	<i>gw.get_edges_in_area(double x0, double y0, double x1, double y1)</i>	returns the list of edges intersecting the rectangular area (<i>x0, y0, x1, y1</i>).
<i>void</i>	<i>gw.save_node_attributes()</i>	...

<i>void</i>	<i>gw.save_edge_attributes()</i>	...
<i>void</i>	<i>gw.save_all_attributes()</i>	...
<i>void</i>	<i>gw.restore_node_attributes()</i>	...
<i>void</i>	<i>gw.restore_edge_attributes()</i>	...
<i>void</i>	<i>gw.restore_all_attributes()</i>	...
<i>void</i>	<i>gw.reset_nodes(long mask = N_ALL)</i>	reset node parameters to their default values.
<i>void</i>	<i>gw.reset_edges(long mask = E_ALL)</i>	reset edge parameters to their default values.
<i>void</i>	<i>gw.reset()</i>	reset node and edge parameters to their default values.
<i>void</i>	<i>gw.reset_defaults()</i>	resets default parameters to their original values.
<i>node</i>	<i>gw.get_edit_node()</i>	returns a node under the current mouse pointer position (<i>nil</i> if there is no node at the current position)
<i>edge</i>	<i>gw.get_edit_edge()</i>	returns an edge under the current mouse pointer position (<i>nil</i> if there is no edge at the current position).
<i>int</i>	<i>gw.get_edit_slider()</i>	returns the number of the slider under the current mouse pointer position (0 if there is no edge slider at the current position).
<i>void</i>	<i>gw.get_bounding_box(double& x0, double& y0, double& x1, double& y1)</i>	computes the coordinates (<i>x0, y0, x1, y1</i>) of a minimal bounding box for the current layout of the graph.
<i>void</i>	<i>gw.get_bounding_box(const list<node>& V, const list<edge>& E, double& x0, double& y0, double& x1, double& y1)</i>	computes the coordinates (<i>x0, y0, x1, y1</i>) of a minimal bounding box for the current layout of sub-graph (<i>V, E</i>).

18.7 The GraphWin (GW) File Format

The *gw*-format is the external graph format of *GraphWin*. It extends LEDA's graph format described in the previous section by additional parameters and attributes for describing graph drawings. Note that the *gw*-format was not defined to be a readable or easy to extend file format (in contrast to the *GML* format that is also supported by GraphWin).

Each *gw* file starts with a LEDA graph followed by a (possibly empty) layout section. An empty layout section indicates that no drawing of the graph is known, e.g. in the input file of a layout algorithm. If a layout section is given, it consists of three parts:

1. global parameters
2. node attributes
3. edge attributes

Global Parameters

The global parameter section consists of 7 lines (with an arbitrary number of inter-mixed comment-lines).

1. version line
The version line specifies the version of the *gw*-format. It consists of the string **GraphWin** followed by a floating-point number (1.32 for the current version of GraphWin).
2. window parameters
scaling wxmin wymin wxmax ymax
This line consists of 5 floating-point numbers specifying the scaling, minimal/maximal x- and y-coordinates of the window (see the *window* class of LEDA).
3. node label font
type size
This line defines the font used for node labels. The *type* value is of type *int*. Possible values (see `gw_font_type`) are
0 (`roman_font`)
1 (`bold_font`)
2 (`italic_font`)
3 (`fixed_font`). The *size* value is of type *int* and defines the size of the font in points.
4. edge label font
type size as above, but defines the font used for edge labels.
5. node index format
format
This line contains a printf-like format string used for constructing the index label of nodes (e.g. `%d`).

6. edge index format

format

This line contains a printf-like format string used for constructing the index label of edges (e.g. %d).

7. multi-edge distance

dist

This line contains a floating-point parameter *dist* that defines the distance used to draw parallel edges.

We close the description of the global parameter section with an example.

```
# version
GraphWin 1.32
# window parameters
1.0 -10.0 -5.0 499.0 517.0
# node font
0 12
# edge font
0 12
# node index string
%d
# edge index string
%d
# multi-edge distance
4.0
```

Node Attributes

The node attribute section contains for each node of the graph a line consisting of the following attributes (separated by blanks). More precisely, the *i*-th line in this section defines the attributes of the *i*-th node of the graph (see section leda-format).

x-coordinate

an attribute of type *double* defining the x-coordinate of the center of the node.

y-coordinate

an attribute of type *double* defining the y-coordinate of the center of the node.

shape

an attribute of type *int* defining the shape of the node. Possible values are (see `gw_node_shape` of GraphWin)

0 (`circle_node`)1 (`ellipse_node`)2 (`square_node`)3 (`rectangle_node`).

border color

an attribute of type *int* defining the color used to draw the boundary line of the node. Possible values are (see the LEDA *color* type)

- 1 (*invisible*)
- 0 (*black*)
- 1 (*white*)
- 2 (*red*)
- 3 (*green*)
- 4 (*blue*)
- 5 (*yellow*)
- 6 (*violet*)
- 7 (*orange*)
- 8 (*cyan*)
- 9 (*brown*)
- 10 (*pink*)
- 11 (*green2*)
- 12 (*blue2*)
- 13 (*grey1*)
- 14 (*grey2*)
- 15 (*grey3*)
- 16 (*ivory*).

border width

an attribute of type *double* defining the width of the border line of the node.

radius1

an attribute of type *double* defining the horizontal radius of the node

radius2

an attribute of type *double* defining the vertical radius of the node

color

an attribute of type *int* defining the color used to fill the interior of the node. See the LEDA *color* type for possible values.

label type

an attribute of type *int* specifying the label type. Possible values (see *gw_label_type* of *GraphWin*) are

- 0 (*no_label*)
- 1 (*user_label*)
- 2 (*data_label*)
- 3 (*index_label*).

label color

an attribute of type *int* defining the color used to draw the label of the node. See the LEDA *color* type for possible values.

label position

an attribute of type *int* defining the label position. Possible values (see *gw_position*

of GraphWin) are
 0 (central_pos)
 1 (northwest_pos)
 2 (north_pos)
 3 (northeast_pos)
 4 (east_pos)
 5 (southeast_pos)
 6 (south_pos)
 7 (southwest_pos)
 8 (west_pos).

user label

an attribute of type **string** defining the user label of the node.

We close this section with an example of a node attribute line that describes a circle node at position (189, 260) with border color *black*, border width 0.5, horizontal and vertical radius 12, interior color *ivory*, label type *index_label*, label position *east_pos*, and an empty user label.

```
# x    y    shape b-clr b-width radius1 radius2  clr l-type l-clr l-pos l-str
189.0 260.0 0      1      0.5     12.0    12.0    16  3      -1   4
```

Edge Attributes:

The edge attribute section contains for each edge of the graph a line consisting of the following attributes (separated by blanks). More precisely, the *i*-th line in this section defines the attributes of the *i*-th edge of the graph (see section *leda-format*).

width

an attribute of type **double** defining the width of the edge.

color

an attribute of type **color** defining the color of the edge.

shape

an attribute of type *int* defining the shape of the edge. Possible values (see *gw_edge_shape* of GraphWin) are

0 (poly_edge)
 1 (circle_edge)
 2 (bezier_edge)
 3 (spline_edge).

style

an attribute of type *int* defining the line style of the edge. Possible values (see the LEDA *line_style* type) are

0 (solid)
 1 (dashed)
 2 (dotted)
 3 (dashed_dotted).

direction

an attribute of type *int* defining whether the edge is drawn as a directed or an undirected edge. Possible values (see `gw_edge_dir` of GraphWin) are

- 0 (`undirected_edge`)
- 1 (`directed_edge`)
- 2 (`redirected_edge`)
- 3 (`bidirected_edge`).

label type

an attribute of type *int* defining the label type of the edge. Possible values (see `gw_label_type` of GraphWin) are

- 0 (`no_label`)
- 1 (`user_label`)
- 2 (`data_label`)
- 3 (`index_label`).

label color

an attribute of type *int* defining the color of the edge label. See the LEDA *color* type for possible values.

label position

an attribute of type *int* defining the position of the label. Possible values (see `gw_position` of GraphWin) are

- 0 (`central_pos`)
- 4 (`east_pos`)
- 8 (`west_pos blue`).

polyline

an attribute of type *list* \langle *point* \rangle defining the polyline used to draw the edge. The list is represented by the number *n* of elements followed by *n* points (x_i, y_i) for $i = 1 \dots n$. The first element of the list is the point where the edge leaves the interior of the source node, the last element is the point where the edge enters the interior of the target node. The remaining elements give the sequence of bends (or control points in case of a bezier or spline edge).

user label

an attribute of type `string` defining the user label of the edge.

We close this section with an example of an edge attribute line that describes a blue solid polygon edge of width 0.5 drawn directed from source to target, with a black user-defined label "my label" at position `east_pos`, centered source and target anchors, and with a bend at position (250, 265).

```
# width clr shape style dir ltype lclr lpos sanch tanch poly lstr
0.5 4 0 0 1 1 1 4 (0,0) (0,0) 3 (202.0,262.0) (250.0,265.0)
```

18.8 Geometry Windows (GeoWin)

1. Definition

An instance of data type *GeoWin* is an editor for *sets of geometric objects*. It can be used for the visualization of result and progression of geometric algorithms. *GeoWin* provides an *interactive interface* and a *programming interface* to visualize and manipulate geometric objects and data structures.

Sets of geometric objects are maintained in so-called *scenes*.

Scenes

Scenes are instances of the various scene data types supported by *GeoWin*. They are used to store collections of geometric objects and attributes of the objects and collections. Furthermore the scene classes have to provide functionality for *GeoWin* to handle the geometric objects of a scene.

Each *scene* stores geometric objects in a *container* (a LEDA-list or STL-list). We call these geometric objects stored in a container of a *scene* the *contents* of a scene. The scenes and their *contents* can be manipulated by the interactive interface and the programming interface of *GeoWin*.

With every *scene* a set of attributes is associated. Most of them describe the visual representation of the scene, for instance the boundary- and fill-color of the objects, the visibility of the scene,... .

We use the type *geo_scene* as the scene item type of *GeoWin*; it may be helpful to view it as pointers to scenes.

We distinguish the following types of scene classes:

1. *Edit Scenes* (type *GeoEditScene<CONTAINER>*)

where *CONTAINER* is the type of the scene's container storing the contents of the scene, for instance *list<point>*. These scenes can be edited by the user through the interactive interface of *GeoWin*. Note that edit scenes have some special features. An important feature is the possibility to *select* objects through the interactive interface. These selected objects have special attributes, see the table of scene attributes.

2. *Result Scenes* (type *GeoResultScene<I, R>*)

These scenes are not independently editable by the user. The contents of result scenes is computed by a user-defined *update function* or *update object* executing a geometric algorithm. This recomputation of the scene contents will be done every time when another scene (this other scene we call the input scene of the result scene)

changes. The contents of the result scene is stored in a container of type R . The input scene must be a *Basic Scene* with a container of type I . The update function $\text{void } (*f_update)(\text{const } I\& \text{ input}, R\& \text{ result})$ gets the contents of this input scene and computes the contents result of the result scene. We say that the result scene *depends* on its input scene.

3. *Basic Scenes* (type $\text{GeoBaseScene}\langle\text{CONTAINER}\rangle$)

Edit Scenes and *Result Scenes* are derived from *Basic Scenes*. The basic scene type works on container types providing an interface as the list of the STL library. More precisely, CONTAINER has to support the following type definitions and STL-like operations:

- *value_type* - the type T of the values the container holds
- *iterator*
- operations $\text{begin}()$ and $\text{end}()$ returning an iterator that can be used for beginning (ending) the traversal of the container
- $\text{void } \text{push_back}(\text{const } T\&)$ for inserting an element at the end of the container
- $\text{iterator } \text{insert}(\text{iterator } it, \text{const } T\&)$ for inserting an element (before it)
- $\text{void } \text{erase}(\text{iterator } it)$ for erasing an element at position it
- operation $\text{bool } \text{empty}()$ returning *true* if the container is empty, false otherwise

That means, that LEDA lists can be used as well as containers.

The programming interface of *GeoWin* provides various operations to create *Edit Scenes* and *Result Scenes*. *Basic Scenes* are not created directly by the operations of the programming interface, but they are used for derivation of the other scene types, and we will find them in the programming interface, when both *Edit* and *Result Scenes* are supported by an operation.

GeoWin - class

We explain some important terms of the *GeoWin* data type. Every instance GW of *GeoWin* can maintain a number of *geo_scenes*.

Visible scenes will be displayed by GW , non-visible scenes will not be displayed. Displayed means, that the contents of the scene will be displayed. A special case is the *active* scene of GW . Every *GeoWin* can have at most one *active* scene. The active scene is an *Edit Scene* with input focus. That means that this scene is currently edited by the user through the interactive interface. Note that the currently active scene will be displayed.

Another important topic is the display order of scenes. Every scene has an associated non-negative z-coordinate. When a scene is created, it gets z-coordinate 0. When GW redraws a scene, the contents of this scene and the contents of its visible dependent scenes is drawn. In the redraw-operation of *GeoWin* the scenes with higher z-coordinates will be drawn in the background of scenes with lower z-coordinate. The scenes with z-coordinate

0 will be drawn on top in the order of their creation in its instance of *GeoWin* (the scene, that was created last and has z-coordinae 0 is the scene on top).

Attributes of scenes

The following attributes are associated with every scene.

Name	Type	Description
<i>active</i>	<i>bool</i>	activity status of a scene
<i>active_line_width</i>	<i>int</i>	line width used for drawing objects of active scenes
<i>client_data</i>	<i>void*</i>	some <i>void*</i> -pointers that can be associated with a scene
<i>color</i>	<i>color</i>	boundary color of non-selected objects
<i>description</i>	<i>string</i>	a string describing the scene
<i>fill_color</i>	<i>color</i>	fill color of objects
<i>line_style</i>	<i>line_style</i>	line style used for drawing objects
<i>line_width</i>	<i>int</i>	line width used for drawing objects of non-active scenes
<i>name</i>	<i>string</i>	the name of the scene
<i>point_style</i>	<i>point_style</i>	point style used for drawing objects
<i>selection_color</i>	<i>color</i>	boundary color selected objects
<i>selection_fill_color</i>	<i>color</i>	fill color of selected objects
<i>show_orientation</i>	<i>bool</i>	disables/enables the drawing of object orientations/directions
<i>text_color</i>	<i>color</i>	text label color
<i>visible</i>	<i>bool</i>	visibility of a scene in its <i>GeoWin</i>
<i>z_order</i>	<i>int</i>	z-coordinate of a scene in its <i>GeoWin</i>

Attributes and parameters of instances of *GeoWin*

Every instance of type *GeoWin* uses the following attributes and parameters. The parameters starting with *d3_* are influencing the 3-d output option of *GeoWin*. This 3-d output option uses the LEDA-class *d3_window* for displaying geometric objects. See also the *d3_window* - Manualpages for a description of the 3-d output parameters.

Name	Type	Description
<i>active_scene</i>	<i>geo_scene</i>	the active scene
<i>bg_color</i>	<i>color</i>	window background color
<i>bg_pixmap</i>	<i>string</i>	name of the used window background pixmap
<i>d3_elimination</i>	<i>bool</i>	<i>true</i> - in the d3-output hidden lines will be eliminated
<i>d3_show_edges</i>	<i>bool</i>	enables/disables the redraw of edges in the d3-output
<i>d3_solid</i>	<i>bool</i>	<i>true</i> - in the d3-output faces will be drawn in different grey scales
<i>grid_dist</i>	<i>double</i>	width of the grid in the drawing area
<i>grid_style</i>	<i>grid_style</i>	style of the grid in the drawing area
<i>show_grid</i>	<i>bool</i>	defines if a grid should be used in the drawing area of the window
<i>show_position</i>	<i>bool</i>	<i>true</i> - the coordinates of the mouse cursor are displayed

The geometric objects

The objects stored in the containers of the scenes have to support input and output operators for streams and the LEDA window and the output operator to the *ps-file*.

Manual overview

The following manual pages have this structure:

- a) Main operations (creation of scenes)
- b) Window operations (initialization of the drawing window)
- c) Scenes and scene groups (get/set - operations for changing attributes)
- d) I/O operations
- e) View operations (zooming)
- f) Parameter operations (get/set - operations for instances of type *GeoWin*)
- g) Event handling
- h) Scene group operations
- i) Further operations (changing of the user interface, 3d output, ...)

```
#include < LEDA/graphics/geowin.h >
```

2. Creation

```
GeoWin GW(const char * label = "GEOWIN");
```

creates a *GeoWin* *GW*. *GW* is constructed with frame label *label*

```
GeoWin GW(int w, int h, const char * label = "GEOWIN");
```

creates a *GeoWin* *GW* with frame label *label* and window size $w \times h$ pixels.

3. Operations

a) Main Operations

In this section you find operations for creating scenes and for starting the interactive mode of GeoWin.

The *new_scene* and *get_objects* operations use member templates. If your compiler does not support member templates, you should use instead the templated functions

geowin_new_scene and *geowin_get_objects* with *GW* as an additional first parameter.

All *new_scene* operations can get as an optional last parameter a pointer to a function that is used to compute the three-dimensional output of the scene. The type of such a function pointer *f* is

```
void (*f)(const T&, d3_window&, GRAPH<d3_point, int>&))
```

where *T* is the type of the container used in the scene (for instance *list<point>*). The function gets a reference to the container of it's scene, a reference to the output *d3_window* and to the parametrized graph describing the three-dimensional output. The function usually adds new nodes and edges to this graph. Note that every edge in the graph must have a reversal edge (and the reversal information has to be set).

Example:

```
void segments_d3(const list<segment>& L, d3_window& W,
                GRAPH<d3_point, int>& H)
{
  GRAPH<d3_point, int> G;
  segment iter;
  forall(iter, L) {
    node v1 = G.new_node(d3_point(iter.source().xcoord(),
                                  iter.source().ycoord(), 0));
    node v2 = G.new_node(d3_point(iter.target().xcoord(),
                                  iter.target().ycoord(), 0));

    edge e1 = G.new_edge(v1, v2);
    edge e2 = G.new_edge(v2, v1);
    G.set_reversal(e1, e2);
  }
  H.join(G);
}
```

In this simple example the function gets a list of segments. For every segment in the list two new nodes and two new edges are created. The reversal information is set for the two edges. At the end the local graph *G* is merged into *H*.

The following templated *new_scene* operation can be used to create edit scenes. The *CONTAINER* has to be a *list<T>* , where *T* is one of the following 2d LEDA kernel type

- *(rat_)point*
- *(rat_)segment*
- *(rat_)line*
- *(rat_)circle*
- *(rat_)polygon*

- *(rat_)gen_polygon*

or a *d3_point* or a *d3_rat_point*. If you want to use the other 2d LEDA kernel types, you have to include *geowin_init.h* and to initialize them for usage in *GeoWin* by calling the *geowin_init_default_type* function at the beginning of *main* (before an object of data type *GW* is constructed). If you want to use the other 3d LEDA kernel types, you have to include *geowin_init_d3.h* and to initialize them for usage in *GeoWin* by calling the *geowin_init_default_type* function at the beginning of *main* (before an object of data type *GW* is constructed).

```
template <class CONTAINER>
```

```
GeoEditScene<CONTAINER>* GW.new_scene(CONTAINER& c)
```

creates a new edit scene and returns a pointer to the created scene. *c* will be the container storing the contents of the scene.

```
template <class CONTAINER>
```

```
GeoEditScene<CONTAINER>* GW.new_scene(CONTAINER& c, string str,
                                       D3_FCN f)
```

creates a new edit scene and returns a pointer to the created scene. *c* will be the container storing the contents of the scene. The name of the scene will be set to *str*.

The following *new_scene* operations can be used to create result scenes. Result scenes use the contents of another scene (the input scene) as input for a function (the update function). This function computes the contents of the result scene. The update function is called every time when the contents of the input scene changes. Instead of using an update function you can use an update object that encapsulates an update function. The type of this update object has to be *geowin_update<I, R>* (*I* - type of the container in the input scene, *R* - type of the container in the result scene) or a class derived from it. A derived class should overwrite the virtual update function

```
void update(const I& in, R& out)
```

of the base class to provide a user defined update function. The class *geowin_update<I, R>* has 3 constructors getting function pointers as arguments:

```
geowin_update(void (*f))(const I& in, R& res)
```

```
geowin_update(void (*f))(const I& in, R::value_type& obj)
```

```
geowin_update(R::value_type (*f))(const I& in)
```

When the update object is constructed by calling the constructor with one of these function pointers, the function *(*f)* will be called in the update method of the update object. The first variant is the normal update function that gets the contents *in* of the input scene and computes the contents *res* of the output scene. In the second variant the contents of the result scene will first be cleared, then the update function will be called and *obj* will

be inserted in the result scene. In the third variant the contents of the result scene will be cleared, and then the object returned by (**f*) will be inserted in the result scene. The class *geowin_update* has also the following virtual functions:

```
bool insert(const InpObject& new)
```

```
bool del(const InpObject& new)
```

```
bool change(const InpObject& old_obj, const InpObject& new_obj)
```

where *new* is a new inserted or deleted object and *old_obj* and *new_obj* are objects before and after a change. *InpObject* is the value type of the container of the input scene. With these functions it is possible to support incremental algorithms. The functions will be called, when in the input scene new objects are added (*insert*), deleted (*del*) or changed when performing a move or rotate operation (*change*). In the base class *geowin_update*<*I, R*> these functions return *false*. That means, that the standard update-function of the update object should be used. But in derived classes it is possible to overwrite these functions and provide user-defined update operations for these three incremental operations. Then the function has to return *true*. That means, that the standard update function of the update object should not be used. Instead the incremental operation performs the update-operation.

It is also possible to provide user defined redraw for a scene. For this purpose we use redraw objects derived from *geowin_redraw*. The derived class has to overwrite the virtual redraw function

```
void draw(window& W, color c1, color c2, double x1, double y1, double x2, double y2)
```

of the base class to provide a user defined redraw function. The first 3 parameters of this function are the redraw window and the first and second drawing color (*color* and *color2*) of the scene. The class *geowin_redraw* has also a virtual method

```
bool draw_container( )
```

that returns *false* in the base class. If you want the user defined redraw of the scene (provided by the redraw function *draw*) and the execution of the 'normal' redraw of the scene as well (output of the objects stored in the container of the scene), you have to overwrite *draw_container* in a derived class by a function returning *true*. A virtual method

```
bool write_postscript(ps_file& PS, color c1, color c2)
```

is provided for output to a LEDA postscript file *PS*. *c1* and *c2* are the first and second drawing color (*color* and *color2*) of the scene. Another class that can be used for user defined redraw is the templated class *geowin_redraw_container*<*CONTAINER*>. This class has as well virtual functions for redraw and postscript output, but provides a slightly changed interface:

```
bool draw(const CONTAINER& c, window& w, color c1, color c2, double, double, double, double)
```

```
bool write_postscript(const CONTAINER& c, ps_file& ps, color c1, color c2)
```

The parameters of these two virtual functions are like the parameters of the members with the same name of *geowin_redraw*, but there is an additional first parameter. This parameter is a reference to the container of the scene that has to be redrawn.

In update- and redraw- functions and objects the following static member functions of the *GeoWin* class can be used:

```
GeoWin * GeoWin::get_call_geowin( )  
geo_scene GeoWin::get_call_scene( )  
geo_scene GeoWin::get_call_input_scene( )
```

The first function returns a pointer to the *GeoWin* of the calling scene, the second returns the calling scene and the third (only usable in update functions/ objects) returns the input scene of the calling scene.

Note that *S* and *R* in the following operations are template parameters. *S* and *R* have to be a *list<T>*, where *T* is a 2d LEDA kernel type, a *d3_point* or a *d3_rat_point*. *S* is the type of the contents of the input scene, *R* the type of the contents of the created result scene. All operations creating result scenes return a pointer to the created result scene.

This section contains three small example programs showing you the usage of the *new_scene* operations for the creation of result scenes. All example programs compute the convex hull of a set of points stored in the container of an input scene *sc_points* and store the computed hull in a result scene *sc_hull*.

```
template <class S, class R>  
GeoResultScene<S, R>* GW.new_scene(void (*f_update)(const S& , R& ), geo_scene sc,  
                                   string str, D3_FCN f = NULL)
```

creates a new result scene with name *str*. The input scene for this new result scene will be *sc*. The update function will be *f_update*.

The first example program shows the usage of the *new_scene* operation taking an update function pointer. The update function computes the convex hull of the points stored in the input scene. The result polygon will be inserted in the container *P* of the result scene.

```
#include <LEDA/graphics/geowin.h>  
#include <LEDA/geo/float_geo_alg.h>  
  
using namespace leda;  
  
void convex_hull(const list<point>& L, list<polygon>& P)  
{ P.clear(); P.append(CONVEX_HULL_POLY(L)); }  
  
int main()  
{  
  GeoWin gw;  
  list<point> LP;
```

```

geo_scene sc_points = gw.new_scene(LP);
geo_scene sc_hull = gw.new_scene(convex_hull, sc_points, "Convex hull");
gw.set_color(sc_hull, blue);
gw.set_visible(sc_hull, true);

gw.edit(sc_points);
return 0;
}

```

```

template <class S, class R>
GeoResultScene<S, R>* GW.new_scene(geowin_update<S, R>& up, list<geo_scene>& infl,
                                   string str, D3_FCN f = NULL)

```

creates a new result scene *scr* with name *str*. The input scene for this new result scene will be the first scene in *infl*. The update object will be *up*. *up* has to be constructed by a call *up(fu, 0)*, where *fu* is a function of type *void fu(const C0&, const C1&, ..., const Cn&, R&)*. *infl* is a list of scenes influencing the result scene. *C0, ..., Cn* are the types of the containers of the scenes in *infl*. When one of the scenes in *infl* changes, *fu* will be called to update the contents of *scr*. *Precondition: infl* must not be empty.

```

template <class S, class R>
GeoResultScene<S, R>* GW.new_scene(geowin_update<S, R>& up, geo_scene sc_input,
                                   string str, D3_FCN f = NULL)

```

creates a new result scene with name *str*. The input scene for this new result scene will be *sc_input*. The update object will be *up*.

The second variant of the example program uses an update object *update*.

```

#include <LEDA/graphics/geowin.h>
#include <LEDA/geo/float_geo_alg.h>

using namespace leda;

int main()
{
  GeoWin gw;
  list<point> LP;

  geo_scene sc_points = gw.new_scene(LP);

  geowin_update<list<point>, list<polygon> > update(CONVEX_HULL_POLY);
  geo_scene sc_hull = gw.new_scene(update, sc_points, "Convex hull");
  gw.set_color(sc_hull, blue);
  gw.set_visible(sc_hull, true);

  gw.edit(sc_points);
}

```

```

return 0;
}

```

```

template <class S, class R>

```

```

void      GW.set_update(geo_scene res, geowin_update<S, R>& up)

```

makes *up* the update object of *res*. *Precondition*: *res* points to a scene of type *GeoResultScene<S, R>* .

```

template <class S, class R>

```

```

void      GW.set_update(geo_scene res, void (*f_update)(const S& , R& ))

```

makes *f_update* the update function of *res*. *Precondition*: *res* points to a scene of type *GeoResultScene<S, R>* .

```

template <class S, class R>

```

```

GeoResultScene<S, R>* GW.new_scene(geowin_update<S, R>& up, geowin_redraw& rd,
                                   geo_scene sc_input, string str,
                                   D3_FCN f = NULL)

```

creates a new result scene with name *str*. The input scene for this new result scene will be *sc_input*. The update object will be *ub*. The redraw object will be *rd*.

The third variant of the example program uses an update and redraw object. We provide a user defined class for update and redraw of the result scene.

```

#include <LEDA/graphics/geowin.h>
#include <LEDA/geo/float_geo_alg.h>

using namespace leda;

class hull_update_redraw : public geowin_update<list<point>, list<polygon> > ,
                          public geowin_redraw
{
    list<polygon> polys;
public:
    void update(const list<point>& L, list<polygon>& P)
    {
        polys.clear();
        polys.append(CONVEX_HULL_POLY(L));
    }

    void draw(window& W,color c1,color c2,double x1,double y1,double x2,double y2)
    {
        polygon piter;
        segment seg;
        forall(piter, polys){
            forall_segments(seg, piter){
                W.draw_arrow(seg, c1);
            }
        }
    }
}

```

```

}
};

int main()
{
    GeoWin gw;
    list<point> LP;

    geo_scene sc_points = gw.new_scene(LP);

    hull_update_redraw up_rd;
    geo_scene sc_hull = gw.new_scene(up_rd, up_rd, sc_points, "Convex hull");
    gw.set_color(sc_hull, blue);
    gw.set_visible(sc_hull, true);

    gw.edit(sc_points);
    return 0;
}

```

```

template <class S, class R>
GeoResultScene<S, R>* GW.new_scene(geowin_update<S, R>& up,
                                   geowin_redraw_container<R>& rd,
                                   geo_scene sc_input, string str,
                                   D3_FCN f = NULL)

```

creates a new result scene with name *str*. The input scene for this new result scene will be *sc_input*. The update object will be *ub*. The redraw container object will be *rd*.

```

template <class CONTAINER>
bool GW.get_objects(CONTAINER& c)

```

If the container storing the contents of the current edit scene has type *CONTAINER*, then the contents of this scene is copied to *c*.

```

template <class CONTAINER>
bool GW.get_objects(geo_scene sc, CONTAINER& c)

```

If the container storing the contents of scene *sc* has type *CONTAINER*, then the contents of scene *sc* is copied to *c*.

```

template <class CONTAINER>
void GW.get_selected_objects(GeoEditScene<CONTAINER> * sc,
                             CONTAINER& cnt)

```

returns the selected objects of scene *sc* in container *cnt*.

```

template <class CONTAINER>

```

```

void          GW.setSelectedObjects( GeoEditScene<CONTAINER> * sc,
                                   const list<typename CONTAINER::iterator>& LIT)
    selects the objects of scene sc described by the con-
    tents of container LIT.

template <class CONTAINER>
void          GW.setSelectedObjects( GeoEditScene<CONTAINER> * sc)
    selects all objects of scene sc.

template <class CONTAINER>
void          GW.setSelectedObjects( GeoEditScene<CONTAINER> * sc,
                                   const rectangle& R)
    selects all objects of scene sc contained in rectangle
    R.

void          GW.edit()
    starts the interactive mode of GW. The operation re-
    turns if either the DONE or Quit button was pressed.

bool          GW.edit(geo_scene sc)
    edits scene sc. Returns false if the Quit-Button was
    pressed, true otherwise.

void          GW.register_window(window& win, bool (*ev_fcn)(window * w, int event,
                                                             int but, double x, double y))
    if you enter the interactive mode of GW in an applica-
    tion, but you want to handle events of other windows
    as well, you can register a callback function ev_fcn for
    your other window win that will be called when events
    associated with win occur. The parameters of ev_fcn
    are the window causing the event, the event that oc-
    curred, the button and the x and y coordinates of the
    position in win. The handler ev_fcn has to return true
    if the interactive mode of GeoWin has to be stopped,
    false otherwise.

```

Simple Animations

The following operation can be used to perform simple animations. One can animate the movement of selected objects of a scene. This can be done in the following way: select a number of objects in an edit scene; then start the animation by calling the *animate* member function. The second parameter of this member function is an object *anim* of type *geowin_animation*, the first parameter is the scene that will be animated. The object *anim* has to be derived from the abstract base class *geowin_animation*. The derived class has to overwrite some methods of the base class:

```

class geowin_animation {
public:
    virtual void init(const GeoWin&) { }
    virtual void finish(const GeoWin&) { }

```

```

virtual bool is_running(const GeoWin&) { return true; }
virtual point get_next_point(const GeoWin&) = 0;
virtual long get_next_action(const GeoWin&)
{ return GEOWIN_STOP_MOVE_SELECTED; }
};

```

At the start and at the end of an animation the member functions *init* and *finish* are called. The animation is stopped if *is_running* returns false. The member functions *get_next_point* and *get_next_action* specify the animation. *get_next_point* delivers the next point of the animation path. *get_next_action* currently can return two values: *GEOWIN_MOVE_SELECTED* (moves the selected objects of the scene) and *GEOWIN_STOP_MOVE_SELECTED* (stops the movement of the selected objects of the scene).

```

bool      GW.animate(geo_scene sc, geowin_animation& anim)
                                starts animation anim for edit scene sc.

```

b) Window Operations

```

void      GW.close()           closes GW .
double    GW.get_xmin()       returns the minimal x-coordinate of the drawing area.
double    GW.get_ymin()       returns the minimal y-coordinate of the drawing area.
double    GW.get_xmax()       returns the maximal x-coordinate of the drawing area.
double    GW.get_ymax()       returns the maximal y-coordinate of the drawing area.
void      GW.display(int x = window::center, int y = window::center)
                                opens GW at (x, y).
window&   GW.get_window()     returns a reference to the drawing window.
void      GW.init(double xmin, double xmax, double ymin)
                                same as window::init(xmin, xmax, ymin, g).
void      GW.init(double x1, double x2, double y1, double y2,
                    int r = GEOWIN_MARGIN)
                                inializes the window so that the rectangle with lower
                                left corner (x1 - r, y1 - r) and upper right corner
                                (x2 + r, y2 + r) is visible. The window must be open.
                                GEOWIN_MARGIN is a default value provided by
                                GeoWin.
void      GW.redraw()         redraws the contents of GW (all visible scenes).
int       GW.set_cursor(int cursor_id = -1)
                                sets the mouse cursor to cursor_id.

```

<i>geo_scene</i>	<i>GW.get_scene_with_name(string nm)</i>	returns the scene with name <i>nm</i> or nil if there is no scene with name <i>nm</i> .
<i>void</i>	<i>GW.activate(geo_scene sc)</i>	makes scene <i>sc</i> the active scene of <i>GW</i> .
<i>int</i>	<i>GW.get_z_order(geo_scene sc)</i>	returns the <i>z</i> -coordinate of <i>sc</i> .
<i>int</i>	<i>GW.set_z_order(geo_scene sc, int n)</i>	sets the <i>z</i> -coordinate of <i>sc</i> to <i>n</i> and returns its previous value.

In front of the scenes of a *GeoWin* object a so-called "user layer" can store some geometric objects illustrating scenes. The following functions let you add some of these objects.

<i>void</i>	<i>GW.add_user_layer_segment(const segment& s)</i>	adds segment <i>s</i> to the segments of the user layer.
<i>void</i>	<i>GW.add_user_layer_circle(const circle& c)</i>	adds circle <i>c</i> to the circles of the user layer.
<i>void</i>	<i>GW.add_user_layer_point(const point& p)</i>	adds point <i>p</i> to the points of the user layer.
<i>void</i>	<i>GW.add_user_layer_rectangle(const rectangle& r)</i>	adds rectangle <i>r</i> to the rectangles of the user layer.
<i>void</i>	<i>GW.remove_user_layer_objects()</i>	removes all objects of the user layer.
<i>void</i>	<i>GW.set_draw_user_layer_fcn(void (*fcn)(GeoWin*))</i>	this function can be used for additional user-defined redraw after drawing the objects of the user layer.
<i>void</i>	<i>GW.set_postscript_user_layer_fcn(void (*fcn)(GeoWin*, ps_file&))</i>	
<i>geo_scene</i>	<i>GW.get_active_scene()</i>	returns the active scene of <i>GW</i> .
<i>bool</i>	<i>GW.is_active(geo_scene sc)</i>	returns true if <i>sc</i> is an active scene in a <i>GeoWin</i> .

The following *get* and *set* operations can be used for retrieving and changing scene parameters. All *set* operations return the previous value.

<i>string</i>	<i>GW.get_name(geo_scene sc)</i>	returns the <i>name</i> of scene <i>sc</i> .
---------------	----------------------------------	--

<i>string</i>	<i>GW.get_name(geo_scenegroup gs)</i> returns the <i>name</i> of scene group <i>gs</i> .
<i>string</i>	<i>GW.set_name(geo_scene sc, string nm)</i> gives scene <i>sc</i> the name <i>nm</i> . If there is already a scene with name <i>nm</i> , another name is constructed based on <i>nm</i> and is given to <i>sc</i> . The operation will return the given name.
<i>color</i>	<i>GW.get_color(geo_scene sc)</i> returns the boundary drawing color of scene <i>sc</i> .
<i>color</i>	<i>GW.set_color(geo_scene sc, color c)</i> sets the boundary drawing color of scene <i>sc</i> to <i>c</i> .
<i>void</i>	<i>GW.set_color(geo_scenegroup gs, color c)</i> sets the boundary drawing color of all scenes in group <i>gs</i> to <i>c</i> .
<i>color</i>	<i>GW.get_selection_color(geo_scene sc)</i> returns the boundary drawing color for selected objects of scene <i>sc</i> .
<i>color</i>	<i>GW.set_selection_color(geo_scene sc, color c)</i> sets the boundary drawing color for selected objects of scene <i>sc</i> to <i>c</i> .
<i>void</i>	<i>GW.set_selection_color(geo_scenegroup gs, color c)</i> sets the boundary drawing color for selected objects of all scenes in <i>gs</i> to <i>c</i> .
<i>color</i>	<i>GW.get_selection_fill_color(geo_scene sc)</i> returns the fill color for selected objects of scene <i>sc</i> .
<i>color</i>	<i>GW.set_selection_fill_color(geo_scene sc, color c)</i> sets the fill color for selected objects of scene <i>sc</i> to <i>c</i> .
<i>line_style</i>	<i>GW.get_selection_line_style(geo_scene sc)</i> returns the line style for selected objects of scene <i>sc</i> .
<i>line_style</i>	<i>GW.set_selection_line_style(geo_scene sc, line_style l)</i> sets the line style for selected objects of scene <i>sc</i> to <i>l</i> .
<i>int</i>	<i>GW.get_selection_line_width(geo_scene sc)</i> returns the line width for selected objects of scene <i>sc</i> .
<i>int</i>	<i>GW.set_selection_line_width(geo_scene sc, int w)</i> sets the line width for selected objects of scene <i>sc</i> to <i>w</i> .

<i>color</i>	<i>GW.get_fill_color(geo_scene sc)</i> returns the fill color of <i>sc</i> .
<i>color</i>	<i>GW.set_fill_color(geo_scene sc, color c)</i> sets the fill color of <i>sc</i> to <i>c</i> . Use color <i>invisible</i> to disable filling.
<i>void</i>	<i>GW.set_fill_color(geo_scenegroup gs, color c)</i> sets the fill color of all scenes in <i>gs</i> to <i>c</i> . Use color <i>invisible</i> to disable filling.
<i>color</i>	<i>GW.get_text_color(geo_scene sc)</i> returns the text color of <i>sc</i> .
<i>color</i>	<i>GW.set_text_color(geo_scene sc, color c)</i> sets the text color of <i>sc</i> to <i>c</i> .
<i>void</i>	<i>GW.set_text_color(geo_scenegroup gs, color c)</i> sets the text color of all scenes in <i>gs</i> to <i>c</i> .
<i>int</i>	<i>GW.get_line_width(geo_scene sc)</i> returns the line width of scene <i>sc</i> .
<i>int</i>	<i>GW.get_active_line_width(geo_scene sc)</i> returns the active line width of <i>sc</i> .
<i>int</i>	<i>GW.set_line_width(geo_scene sc, int w)</i> sets the line width for scene <i>sc</i> to <i>w</i> .
<i>void</i>	<i>GW.set_line_width(geo_scenegroup gs, int w)</i> sets the line width for all scenes in <i>gs</i> to <i>w</i> .
<i>int</i>	<i>GW.set_active_line_width(geo_scene sc, int w)</i> sets the active line width of scene <i>sc</i> to <i>w</i> .
<i>void</i>	<i>GW.set_active_line_width(geo_scenegroup gs, int w)</i> sets the active line width for all scenes in <i>gs</i> to <i>w</i> .
<i>line_style</i>	<i>GW.get_line_style(geo_scene sc)</i> returns the line style of <i>sc</i> .
<i>line_style</i>	<i>GW.set_line_style(geo_scene sc, line_style l)</i> sets the line style of scene <i>sc</i> to <i>l</i> .
<i>void</i>	<i>GW.set_line_style(geo_scenegroup gs, line_style l)</i> sets the line style of all scenes in <i>gs</i> to <i>l</i> .
<i>bool</i>	<i>GW.get_visible(geo_scene sc)</i> returns the visible flag of scene <i>sc</i> .

- bool* `GW.set_visible(geo_scene sc, bool v)`
sets the visible flag of scene *sc* to *v*.
- void* `GW.set_visible(geo_scenegroup gs, bool v)`
sets the visible flag of all scenes in *gs* to *v*.
- void* `GW.set_all_visible(bool v)`
sets the visible flag of all scenes that are currently in *GW* to *v*.
- point_style* `GW.get_point_style(geo_scene sc)`
returns the point style of *sc*.
- point_style* `GW.set_point_style(geo_scene sc, point_style p)`
sets the point style of *sc* to *p*
- void* `GW.set_point_style(geo_scenegroup gs, point_style p)`
sets the point style of all scenes in *gs* to *p*
- bool* `GW.get_cyclic_colors(geo_scene sc)`
returns the cyclic colors flag for editable scene *sc*.
- bool* `GW.set_cyclic_colors(geo_scene sc, bool b)`
sets the cyclic colors flag for editable scene *sc*. If the cyclic colors flag is set, the new inserted objects of the scene get color *counter*%16, where *counter* is the object counter of the scene.
- string* `GW.get_description(geo_scene sc)`
returns the description string of scene *sc*.
- string* `GW.set_description(geo_scene sc, string desc)`
sets the description string of scene *sc* to *desc*. The description string has the task to describe the scene in a more detailed way than the name of the scene does.
- bool* `GW.get_show_orientation(geo_scene sc)`
returns the show orientation/direction parameter of scene *sc*
- bool* `GW.set_show_orientation(geo_scene sc, bool o)`
sets the show orientation/direction parameter of scene *sc* to *o*.
- void** `GW.get_client_data(geo_scene sc, int i = 0)`
returns the *i*-th client data pointer of of scene *sc*. *Pre-condition*: *i* < 16.

- void** *GW.set_client_data(geo_scene sc, void * p, int i = 0)*
sets the *i*-th client data pointer of scene *sc* to *p* and returns its previous value. *Precondition: i < 16.*
- void* *GW.set_handle_defining_points(geo_scene sc, geowin_defining_points gdp)*
sets the attribute for handling of defining points of editable scene (**sc*) to *gdp*. Options for *gdp* are *geowin_show* (show the defining points of all objects of the scene, *geowin_hide* (hide the defining points of all objects of the scene) and *geowin_highlight* (shows only the defining points of the object under the mouse-pointer).
- geowin_defining_points* *GW.get_handle_defining_points(geo_scene sc)*
returns the attribute for handling of defining points of editable scene (**sc*).

The following operations can be used for getting/setting a flag influencing the behaviour of incremental update operations in result scenes. If *update_state* is *true* (default) : if the first incremental operation returns false , incremental update loop will be left *false* : the incremental update loop will be executed until the end
You can also set an *update_limit* for the incremental update operations. If a number of objects bigger than this limit will be added/deleted/changed, the incremental update will not be executed. Instead the "normal" scene update operation will be used.

- bool* *GW.get_incremental_update_state(geo_scene sc)*
returns the incremental update flag of scene *sc*.
- bool* *GW.set_incremental_update_state(geo_scene sc, bool us)*
sets the incremental update flag of scene *sc* to *us*.
- int* *GW.get_incremental_update_limit(geo_scene sc)*
returns the incremental update limit of scene *sc*.
- int* *GW.set_incremental_update_limit(geo_scene sc, int l)*
sets the incremental update limit of scene *sc* to *l*.

It is not only possible to assign (graphical) attributes to a whole scene.

The following operations can be used to set/get individual attributes of objects in scenes. All set operations return the previous value. The first parameter is the scene, where the object belongs to. The second parameter is a generic pointer to the object or an iterator pointing to the position of the object in the container of a scene. Precondition: the object belongs to the scene (is in the container of the scene).

Note that you cannot use a pointer to a copy of the object.

The following example program demonstrates the setting of individual object attributes in an update member function of an update class:

```

#include <LEDA/graphics/geowin.h>
#include <LEDA/geo/rat_geo_alg.h>

using namespace leda;

class attr_update : public geowin_update<list<rat_point>, list<rat_circle> >
{
void update(const list<rat_point>& L, list<rat_circle>& C)
{
    GeoWin* GW_ptr = GeoWin::get_call_geowin();
    GeoBaseScene<list<rat_circle> >* aec =
        (GeoBaseScene<list<rat_circle> >*) GeoWin::get_call_scene();

    C.clear();
    if (! L.empty()) {
        ALL_EMPTY_CIRCLES(L,C);

        // now set some attributes
        list<rat_circle>::iterator it = C.begin();
        int cw=0;
        for(;it!=C.end();it++) {
            GW_ptr->set_obj_fill_color(aec,it,color(cw % 15));
            GW_ptr->set_obj_color(aec,it,color(cw % 10));
            cw++;
        }
    }
};

int main()
{
    GeoWin GW("All empty circles - object attribute test");

    list<rat_point> L;
    geo_scene input = GW.new_scene(L);
    GW.set_point_style(input, disc_point);

    attr_update aec_help;
    geo_scene aec = GW.new_scene(aec_help, input, string("All empty circles"));

    GW.set_all_visible(true);
    GW.edit(input);
    return 0;
}

                if there is an object o in the container of scene sc with
                o == obj the line width of o is assigned to l and true
                is returned. Otherwise false is returned.
```

```
template <class T>
```

```
bool          GW.set_obj_line_width(GeoBaseScene<T> * sc,
                const typename T::value_type& obj, int l,
                bool all = true)
                if there is an object o in the container of scene sc with
                o == obj the line width of o is set to l and true will
                be returned. Otherwise false will be returned.
```

```
template <class T>
```

```
string        GW.get_obj_label(GeoBaseScene<T> * sc, void * adr)
                returns the label of the object at (*adr).
```

```
template <class T>
```

```
string        GW.get_obj_label(GeoBaseScene<T> * sc, typename T::iterator it)
                returns the label of the object it points to.
```

```
template <class T>
string      GW.set_obj_label(GeoBaseScene<T> * sc, void * adr, string lb)
                                sets the label of the object at (*adr) to lb.
```

```
template <class T>
string      GW.set_obj_label(GeoBaseScene<T> * sc, typename T::iterator it,
                                string lb)
                                sets the label of the object it points to to lb.
```

Object texts

The following operations can be used to add/retrieve objects of type *geowin_text* to objects in scenes. The class *geowin_text* is used to store graphical representations of texts. It stores a string (the text) and the following attributes:

Name	Type	Description
<i>font_type</i>	<i>geowin_font_type</i>	font type
<i>size</i>	<i>double</i>	font size
<i>text_color</i>	<i>color</i>	color of the text
<i>user_font</i>	<i>string</i>	font name (if <i>font_type</i> = <i>user_font</i>)
<i>x_offset</i>	<i>double</i>	offset in <i>x</i> -direction to drawing position
<i>y_offset</i>	<i>double</i>	offset in <i>y</i> -direction to drawing position

The enumeration type *geowin_font_type* has the following set of integral constants: *roman_font*, *bold_font*, *italic_font*, *fixed_font* and *user_font*.

The class *geowin_text* has the following constructors:

```
geowin_text(string t, double ox, double oy, geowin_font_type ft,
            double sz, string uf, color c = black);
geowin_text(string t, geowin_font_type ft, double sz);
geowin_text(string t);
```

The arguments are: *t* - the text, *ox*, *oy* - the x/y offsets, *ft* - the font type, *sz* - the font size, *uf* - the user font and *c* - the text color. If a text is associated with an object, it will be drawn centered at the center of the bounding box of the object translated by the *x/y* - offset parameters. Note that it is also possible to add texts to a whole scene and to instances of class *GeoWin*. Then the *x/y* - offset parameters specify the position (see *add_text* operation).

```
template <class T>
bool      GW.get_obj_text(GeoBaseScene<T> * sc, void * adr, geowin_text& gt)
                                Gets the text associated with the object at adr in the
                                container of scene sc and assigns it to gt. If no text
                                is associated with the object, false will be returned,
                                otherwise true.
```

```
template <class T>
bool      GW.get_obj_text(GeoBaseScene<T> * sc, typename T::iterator it,
                        geowin_text& gt)
```

Gets the text associated with the object *it* points to and assigns it to *gt*. If no text is associated with the object, *false* will be returned, otherwise *true*.

```
template <class T>
void      GW.set_obj_text(GeoBaseScene<T> * sc, void * adr, const geowin_text& gt)
```

Assigns *gt* to the object at *adr* in scene *sc*.

```
template <class T>
void      GW.set_obj_text(GeoBaseScene<T> * sc, typename T::iterator it,
                        const geowin_text& gt)
```

Assigns *gt* to the object *it* points to in scene *sc*.

```
template <class T>
void      GW.reset_obj_attributes(GeoBaseScene<T> * sc)
```

deletes all individual attributes of objects in scene (**sc*).

d) Input and Output Operations

```
void      GW.read(geo_scene sc, istream& is)
```

reads the contents of *sc* from input stream *is*. Before the contents of *sc* is cleared.

```
void      GW.write(geo_scene sc, ostream& os)
```

writes the contents of *sc* to output stream *os*.

```
void      GW.write_active_scene(ostream& os)
```

writes the contents of the active scene of *GW* to output stream *os*.

e) View Operations

```
void      GW.zoom_up()
```

The visible range is reduced to the half.

```
void      GW.zoom_down()
```

The visible range is doubled.

```
void      GW.fill_window()
```

changes window coordinate system, so that the objects of the currently active scene fill the window.

```
void      GW.reset_window()
```

resets the visible range to the values that were current when constructing *GW*.

f) Parameter Operations

The following operations allow the set and retrieve the various parameters of *GeoWin*.

<i>string</i>	<code>GW.get_bg_pixmap()</code>	returns the name of the current background pixmap.
<i>string</i>	<code>GW.set_bg_pixmap(string pix_name)</code>	changes the window background pixmap to pixmap with name <i>pix_name</i> . Returns the name of the previous background pixmap.
<i>color</i>	<code>GW.get_bg_color()</code>	returns the current background color.
<i>color</i>	<code>GW.set_bg_color(const color& c)</code>	sets the background color to <i>c</i> and returns its previous value.
<i>color</i>	<code>GW.get_user_layer_color()</code>	returns the current color of the user layer.
<i>color</i>	<code>GW.set_user_layer_color(const color& c)</code>	sets the user layer color to <i>c</i> and returns its previous value.
<i>int</i>	<code>GW.get_user_layer_line_width()</code>	returns the current line width of the user layer.
<i>int</i>	<code>GW.set_user_layer_line_width(int lw)</code>	sets the user layer line width to <i>lw</i> and returns its previous value.
<i>bool</i>	<code>GW.get_show_grid()</code>	returns true, if the grid will be shown, false otherwise.
<i>bool</i>	<code>GW.set_show_grid(bool sh)</code>	sets the show grid flag to <i>sh</i> and returns the previous value.
<i>double</i>	<code>GW.get_grid_dist()</code>	returns the grid width parameter.
<i>double</i>	<code>GW.set_grid_dist(double g)</code>	sets the grid width parameter to <i>g</i> and returns the previous value.
<i>grid_style</i>	<code>GW.get_grid_style()</code>	returns the grid style parameter.
<i>grid_style</i>	<code>GW.set_grid_style(grid_style g)</code>	sets the grid style parameter to <i>g</i> and returns the previous value.
<i>bool</i>	<code>GW.get_show_position()</code>	returns true, if the mouse position will be shown, false otherwise.

- Pre add handler
- Pre add change handler
- Post add handler
- Pre delete handler
- Post delete handler
- Start, Pre, Post and End change handler

The add handlers will be called when a user tries to add an object to an edit scene in `GeoWin`, the delete handlers will be called when the user tries to delete an object and the change handlers will be called when the user tries to change an object (for instance by moving it). The templated set operations for setting handlers uses member templates. If your compiler does not support member templates, you should use instead the templated functions `geowin_set_HANDLER`, where `HANDLER` is one the following handlers. All handling functions get as the first parameter a reference to the `GeoWin`, where the scene belongs to.

```
template <class T, class F>
```

```
bool      GW.set_pre_add_handler(GeoEditScene<T> * sc, F handler)
```

sets the handler that is called before an object is added to (`*sc`). `handler` must have type `bool (*handler)(GeoWin&, const T::value_type &)`. `handler` gets a reference to the added object. If `handler` returns false, the object will not be added to the scene.

```
template <class T, class F>
```

```
bool      GW.set_post_add_handler(GeoEditScene<T> * sc, F handler)
```

sets the handler that is called after an object is added to (`*sc`). `handler` must have type `void (*handler)(GeoWin&, const T::value_type &)`. `handler` gets a reference to the added object.

```
template <class T, class F>
```

```
bool      GW.set_pre_del_handler(GeoEditScene<T> * sc, F handler)
```

sets the handler that is called before an object is deleted from (`*sc`). `handler` must have type `bool (*handler)(GeoWin&, const T::value_type &)`. `handler` gets a reference to the added object. If `handler` returns true, the object will be deleted, if `handler` returns false, the object will not be deleted.

```
template <class T, class F>
```

```
bool      GW.set_post_delete_handler( GeoEditScene<T> * sc, F handler)
```

sets the handler that is called after an object is deleted from (*sc). *handler* must have type `void (*handler)(GeoWin&, const T::value_type &)`.

```
template <class T, class F>
```

```
bool      GW.set_start_change_handler( GeoEditScene<T> * sc, F handler)
```

sets the handler that is called when a geometric object from (*sc) starts changing (for instance when you move it or rotate it). *handler* must have type `bool (*handler)(GeoWin&, const T::value_type &)`. The handler function gets a reference to the object.

```
template <class T, class F>
```

```
bool      GW.set_pre_move_handler( GeoEditScene<T> * sc, F handler)
```

sets the handler that is called before every move operation. *handler* must have type `bool (*handler)(GeoWin&, const T::value_type &, double x, double y)`. The handler gets as the second parameter a reference to the object, as the third parameter and fourth parameter the move vector. If the handler returns true, the change operation will be executed, if the handler returns false, it will not be executed.

```
template <class T, class F>
```

```
bool      GW.set_post_move_handler( GeoEditScene<T> * sc, F handler)
```

sets the handler that is called after every move operation. *handler* must have type `void (*handler)(GeoWin&, const T::value_type &, double x, double y)`. The handler gets as the second parameter a reference to the object, as the third parameter and fourth parameter the move vector.

```
template <class T, class F>
```

```
bool      GW.set_pre_rotate_handler( GeoEditScene<T> * sc, F handler)
```

sets the handler that is called before every rotate operation. *handler* must have type `bool (*handler)(GeoWin&, const T::value_type &, double x, double y, double a)`. If the handler returns true, the rotate operation will be executed, if the handler returns false, it will not be executed.

```
template <class T, class F>
```

```
bool      GW.set_post_rotate_handler(GeoEditScene<T> * sc, F handler)
```

sets the handler that is called after every rotate operation. *handler* must have type `void (*handler)(GeoWin&, const T::value_type&, double x, double x, double a)`.

```
template <class T, class F>
bool      GW.set_end_change_handler(GeoEditScene<T> * sc, F handler)
```

sets the handler that is called when a geometric object from (*sc*) ends changing. *handler* gets the object as the second parameter. *handler* must have type `void (*handler)(GeoWin&, const T::value_type &)`.

Generator functions: The following operation can be used to set a generator function for an edit scene. The operation uses member templates. If your compiler does not support member templates, you should use instead the templated function `geowin_set_generate_fcn`.

```
template <class T>
bool      GW.set_generate_fcn(GeoEditScene<T> * sc, void (*f)(GeoWin& gw,
T& L))
```

sets the generator function for edit scene (*sc*). The function gets the `GeoWin` where (*sc*) belongs to and a reference to the container *L* of (*sc*). The function should write the generated objects to *L*.

Editing of objects in a scene: It is possible to edit single objects in an editable scene. For this purpose an `edit_object` - function can be set for editable scenes. This function has type

```
void (*f)(GeoWin& gw, T& obj, int nr)
```

where *gw* is the `GeoWin`-object where the scene belongs to, *obj* is a reference to the object that will be edited and *nr* is the edit mode of the scene.

```
template <class T, class T2>
bool      GW.set_edit_object_fcn(GeoEditScene<T> * sc, T2 f)
```

sets the edit object - function of scene *sc* to *f*.

```
template <class T>
void*     GW.get_edit_object_fcn(GeoEditScene<T> * sc)
```

returns the edit object - function of scene *sc* .

Transformation objects:

`GeoWin` supports affine transformations of selected objects in editable scenes for the LEDA rat- and float-kernel classes. The used transformation classes are `rat_transform` and `transform` respectively. The following class templates can be used to instantiate transformation objects. They are derived from type `geowin_transform`.

```
geowin_gui_rat_transform<KERNEL_CLASS>
geowin_gui_transform<KERNEL_CLASS>
```

where *KERNELCLASS* is a class of the LEDA rat- or float-kernel. The default is that no transformation objects are associated with editable scenes.

```
template <class S, class GeoObj>
void      GW.set_transform(GeoEditScene<S> * sc,
                          geowin_transform<GeoObj>& trans)
                          makes trans the transformation object of edit scene
                          sc.
```

Input objects: The following operation can be used to set an input object for an edit scene. The operation uses member templates. If your compiler does not support member templates, you should use instead the templated functions prefixed with *geowin*. A `GeoInputObject<GeoObj>` has the following virtual functions:

```
void operator()(GeoWin& gw, list<GeoObj>& L);
```

This virtual function is called for the input of objects. The new objects have to be returned in *L*.

```
void options(GeoWin& gw);
```

This function is called for setting options for the input object.

```
template <class T>
bool      GW.set_input_object(GeoEditScene<T> * sc,
                              const GeoInputObject<typename T::value_type>& obj,
                              string name)
                              sets the input object obj for edit scene (*sc). The
                              function gets the GeoWin where (*sc) belongs to and
                              a reference to a list L. The function must write the
                              new objects to L.
```

```
template <class T>
bool      GW.add_input_object(GeoEditScene<T> * sc,
                              const GeoInputObject<typename T::value_type>& obj,
                              string name)
                              adds the input object obj to the list of available input
                              objects of edit scene (*sc) without setting obj as input
                              object.
```

```
template <class T>
```

- void* *GW.set_draw_object_fcn*(*GeoBaseScene*<*T*> * *sc*,
 window& (**fcn*)(*window*& ,
 const typename T::value_type& , *int w*))
 sets a function *fcn* for scene (**sc*) that will be called
 for drawing the objects of scene (**sc*). If no such
 function is set (the default), the output operator is
 used.
- void* *GW.set_activate_handler*(*geo_scene sc*, *void (*f)(geo_scene)*)
 sets a handler function *f* that is called with *sc* as
 parameter when the user activates *sc*.
- void* *GW.set_edit_loop_handler*(*bool (*f)(const GeoWin& gw)*)
 sets a handler function *f* that is called periodically in
 the interactive mode. If this handler returns *true*, we
 will leave the interactive mode.
- void* *GW.set_quit_handler*(*bool (*f)(const GeoWin& gw)*)
 sets a handler function *f* that is called when the user
 clicks the quit menu button. *f* should return *true* for
 allowing quitting, *false* otherwise.
- void* *GW.set_done_handler*(*bool (*f)(const GeoWin& gw)*)
 sets a handler function *f* that is called when the user
 clicks the done menu button. *f* should return *true* for
 allowing quitting, *false* otherwise.
- int* *GW.set_edit_mode*(*geo_scene sc*, *int emode*)
 sets the edit mode of scene *sc* to *emode*.
- int* *GW.get_edit_mode*(*geo_scene sc*)
 return the edit mode of scene *sc*.

h) Scene group Operations

GeoWin can manage scenes in groups. It is possible to add and remove scenes to/from groups. Various parameters and dependences can be set for whole groups. Note that *geo_scenegroup* is a pointer to a scene group.

- geo_scenegroup* *GW.new_scenegroup*(*string name*)
 Creates a new scene group with name *name* and re-
 turns a pointer to it.
- geo_scenegroup* *GW.new_scenegroup*(*string name*, *const list<geo_scene>& LS*)
 Creates a new scene group *name* and adds the scenes
 in *LS* to this group.
- void* *GW.insert*(*geo_scenegroup gs*, *geo_scene sc*)
 adds *sc* to scene group *gs* .

bool *GW.del(geo_scenegroup gs, geo_scene sc)*
removes *sc* from scene group *gs* and returns true, if
the operation was succesful (false: *sc* was not in *gs*).

i) Further Operations

int *GW.set_button_width(int w)*
sets the width of the scene visibility buttons in *GW*
and returns the previous value.

int *GW.set_button_height(int h)*
sets the height of the scene visibility buttons in *GW*
and returns the previous value.

You can associate a) buttons with labels or b) bitmap buttons with the visibility of a scene in GeoWin. You cannot use a) and b) at the same time. The following operations allow you to use add such visibility buttons to GeoWin. Note that before setting bitmap buttons with the *set_bitmap* operation you have to set the button width and height.

void *GW.set_label(geo_scene sc, string label)*
associates a button with label *label* with the visibility
of scene *sc*.

void *GW.set_bitmap(geo_scene sc, unsigned char * bitmap)*
associates a button with bitmap *bitmap* with the vis-
ibility of scene *sc*.

void *GW.add_scene_buttons(const list<geo_scene>& Ls, const list<string>& Ln)*
add a multiple choice panel for visibility of the scenes
in *Ls* to *GW*. The button for the n-th scene in *Ls*
gets the n-th label in *Ln*.

void *GW.add_scene_buttons(const list<geo_scene>& Ls, int w, int h,
 unsigned char **bm)*
add a multiple choice panel for visibility of the scenes
in *Ls* to *GW*. The button for the n-th scene in *Ls*
gets the n-th bitmap in *bm*. The bitmaps have width
w and height *h*.

list<geo_scene> *GW.get_scenes()* returns the scenes of *GW*.

list<geo_scenegroup> *GW.get_scenegroups()*
returns the scene groups of *GW*.

list<geo_scene> *GW.get_scenes(geo_scenegroup gs)*
returns the scenes of group *gs*.

list<geo_scene> *GW.get_visible_scenes()*
returns the visible scenes of *GW*.

<i>void</i>	<i>GW.add_dependence(geo_scene sc1, geo_scene sc2)</i>	makes <i>sc2</i> dependent from <i>sc1</i> . That means that <i>sc2</i> will be updated when the contents of <i>sc1</i> changes.
<i>void</i>	<i>GW.del_dependence(geo_scene sc1, geo_scene sc2)</i>	deletes the dependence of scene <i>sc2</i> from <i>sc1</i> .
<i>void</i>	<i>GW.set_frame_label(const char * label)</i>	makes <i>label</i> the frame label of <i>GW</i> .
<i>int</i>	<i>GW.open_panel(panel& P)</i>	displays panel <i>P</i> centered on the drawing area of <i>GW</i> , disables the menu bar of <i>GW</i> and returns the result of <i>P.open()</i> .
<i>void</i>	<i>GW.add_text(const geowin_text& gt)</i>	adds a text <i>gt</i> to <i>GW</i> .
<i>void</i>	<i>GW.remove_texts()</i>	removes all texts from <i>GW</i> (but not from the scenes of <i>GW</i>).
<i>void</i>	<i>GW.add_text(geo_scene sc, const geowin_text& gt)</i>	adds a text <i>gt</i> to scene <i>sc</i> .
<i>void</i>	<i>GW.remove_texts(geo_scene sc)</i>	removes all texts from scene <i>sc</i> .
<i>void</i>	<i>GW.enable_menus()</i>	enables the menus of <i>GW</i> .
<i>void</i>	<i>GW.disable_menus()</i>	disables the menus of <i>GW</i> , but not the <i>User</i> menu.
<i>double</i>	<i>GW.version()</i>	returns the <i>GeoWin</i> version number.
<i>void</i>	<i>GW.message(string msg)</i>	displays message <i>msg</i> on top of the drawing area. If <i>msg</i> is the empty string, a previously written message is deleted.
<i>void</i>	<i>GW.msg_open(string msg)</i>	displays message <i>msg</i> in the message window of <i>GW</i> . If the message window is not open, it will be opened.
<i>void</i>	<i>GW.msg_close()</i>	closes the message window.
<i>void</i>	<i>GW.msg_clear()</i>	clears the message window.

- void* `GW.set_d3_fcn(geo_scene sc, void (*f)(geo_scene gs, d3_window& W,
GRAPH<d3_point, int>& H)`
sets a function for computing 3d output. The parameters of the function are the *geo_scene* for that it will be set and a function pointer. The function *f* will get the scene for that it was set and the reference to a *d3_window* that will be the output window.
- D3_FCN* `GW.get_d3_fcn(geo_scene sc)`
returns the function for computing 3d output that is set for scene *sc*. The returned function has pointer type *void* (*)(*geo_scene*, *d3_window*&, *GRAPH*<*d3_point*, *int*>&).
- GeoWin can be pinned at a point in the plane. As standard behavior it is defined that moves of geometric objects will be rotations around the pin point.
- bool* `GW.get_pin_point(point& p)`
returns the pin point in *p* if it is set.
- void* `GW.set_pin_point(point p)`
sets the pin point to *p*.
- void* `GW.del_pin_point()` deletes the pin point.
- void* `GW.add_help_text(string name)`
adds the help text contained in *name.hlp* with label *name* to the help menu of the main window. The file *name.hlp* must exist either in the current working directory or in `$LEDAROOT/incl/Help`. Note that this operation must be called before *gw.display()*.
- void* `GW.add_special_help_text(string name, bool auto_display = false)`
adds one help text contained in *name.hlp* to the menu of the main window. The file *name.hlp* must exist either in the current working directory or in `$LEDAROOT/incl/Help`. Note that this operation must be called before *gw.display()*. If *auto_display* is true, this help text will be displayed, when the main window is displayed.
- template* <*class* *T*>
int `GW.get_limit(GeoEditScene<T> * es)`
returns the limit of edit scene *es* (a negative number will be returned, if there is no limit).
- template* <*class* *T*>

int *GW.set_limit(GeoEditScene<T> * es, int limit)*

sets the limit of edit scene *es* to *limit* and returns the previous value.

The templated *add_user_call* operation uses member templates. If your compiler does not support member templates, you should use instead the templated function *geowin_add_user_call* with *GW* as an additional first parameter.

template <class *F*>

void *GW.add_user_call(string label, F f)*

adds a menu item *label* to the "User" menu of *GW*. The user defined function *void geo_call(GeoWin&, F, string)* is called whenever this menu button was pressed with parameters *GW*, *f* and *label*. This menu definition has to be finished before *GW* is opened.

Import- and export objects can be used to import and export the contents of scenes in various formats.

The classes *geowin_import* and *geowin_export* are used for implementing import- and export objects. The classes *geowin_import* and *geowin_export* have virtual () - operators:

virtual void operator()(geo_scene sc, string filename)

This virtual operator can be overwritten in derived classes to provide import and export functionality for own formats. The first parameter is the scene *sc* that will be used as source for the output or target for the input. The second parameter *filename* is the name of the input (import objects) or output (export objects) file.

void *GW.add_import_object(geo_scene sc, geowin_import& io, string name, string desc)*

Adds an import object *io* to scene *sc*. The import object gets the name *name* and the description *desc*.

void *GW.add_export_object(geo_scene sc, geowin_export& eo, string name, string desc)*

Adds an export object *eo* to scene *sc*. The export object gets the name *name* and the description *desc*.

4. Non-Member Functions

*GeoWin** *get_geowin(geo_scene sc)*

returns a pointer to the *GeoWin* of *sc*.

template <class *CONTAINER*>

bool *get_objects(geo_scene sc, CONTAINER& c)*

If the contents of scene *sc* matches type *CONTAINER*, then the contents of scene *sc* is copied to *c*.

18.9 Windows for 3d visualization (*d3_window*)

1. Definition

The data type *d3_window* supports three-dimensional visualization. It uses a LEDA window to visualize and animate three-dimensional drawings of graph. For this purpose we need to assign positions in 3d space to all *nodes* of the graph (see *init*-operations and *set_position*-operation). The *edges* of the visualized graph are drawn as straight-line-segments between the 3d positions of their source and target *nodes*. Note all edges of the graph must have a reversal edge.

If the graph to be shown is a planar map the *faces* can be shaded in different grey scales (if the *solid* flag is *true*).

The graph can be drawn with the *draw*-operation and animated with the *move*-operation. The *draw*-operation draws a frontal projection of the graph on the output window. The *move*-operation starts a simple animation mode. First it *draws* the graph, then it rotates it (the rotation depends on the *x_rotation* and *y_rotation* flags and the mouse position) and finally returns the pressed mouse button.

Every object of type *d3_window* maintains a set of parameters:

- *x_rotation* (type *bool*); if *true*, rotation about the *x*-axis is enabled during a *move* operation
- *y_rotation* (type *bool*); if *true*, rotation about the *y*-axis is enabled during a *move* operation
- *elim* (type *bool*); if *true*, hidden lines will be eliminated
- *solid* (type *bool*); if *true*, faces have to be drawn in different grey scales
- *draw_edges* (type *bool*) enables/disables the redraw of edges
- *message* (type *string*) is the message that will be displayed on top of the drawing area of the output window

In addition, a *d3_window* stores information assigned to the nodes and edges of the visualized graph.

- *color* (type *color*) information for nodes and edges
- *position* (three-dimensional *vectors*) information for the nodes
- *arrow* (type *bool*) information for the edges (define whether or not edges have to be drawn as arrows)

```
#include < LEDA/graphics/d3_window.h >
```

2. Creation

```
d3_window D(window& W, const graph& G, double rot1 = 0, double rot2 = 0);
```

creates an instance D of the data type $d3_window$. The output window of D is W . The visualized graph is G .

```
d3_window D(window& W, const graph& G, const node_array<vector>& pos);
```

creates an instance D of the data type $d3_window$. The output window of D is W . The visualized graph is G . The positions of the nodes are given in pos . *Precondition*: the vectors in pos are three-dimensional.

```
d3_window D(window& W, const graph& G, const node_array<rat_vector>& pos);
```

creates an instance D of the data type $d3_window$. The output window of D is W . The visualized graph is G . The positions of the nodes are given in pos . *Precondition*: the vectors in pos are three-dimensional.

3. Operations

```
void D.init(const node_array<vector>& pos)
```

initializes D by setting the node positions of the visualized graph to the positions given in pos . *Precondition*: the vectors in pos are three-dimensional.

```
void D.init(const node_array<rat_vector>& pos)
```

initializes D by setting the node positions of the visualized graph to the positions given in pos . *Precondition*: the vectors in pos are three-dimensional.

```
void D.init(const graph& G, const node_array<vector>& pos)
```

initializes D by setting the visualized graph to G and the node positions of the visualized graph to the positions given in pos . *Precondition*: the vectors in pos are three-dimensional.

```
void D.draw()
```

draws the contents of D (see also *Definition*).

<i>int</i>	<i>D.move()</i>	animates the contents of <i>D</i> until a button is pressed and returns the pressed mouse button. If the movement is stopped or no mouse button is pressed, <i>NO_BUTTON</i> will be returned, else the number of the pressed mouse button will be returned (see also <i>Definition</i> and the <i>get_mouse</i> operation of the <i>window</i> data type).
<i>int</i>	<i>D.get_mouse()</i>	does the same as <i>move</i> .
<i>int</i>	<i>D.read_mouse()</i>	calls <i>move</i> as long as <i>move</i> returns <i>NO_BUTTON</i> . Else the movement is stopped, and the number of the pressed mouse button is returned.
<i>void</i>	<i>D.set_position(node v, double x, double y, double z)</i>	sets the position of node <i>v</i> in the visualized graph <i>D</i> to (x, y, z) .

Get- and set-operations

The following operations can be used to get and set the parameters of *D*. The set-operations return the previous value of the parameter.

<i>bool</i>	<i>D.get_x_rotation()</i>	returns <i>true</i> , if <i>D</i> has rotation about the <i>x</i> -axis enabled, <i>false</i> otherwise.
<i>bool</i>	<i>D.get_y_rotation()</i>	returns <i>true</i> , if <i>D</i> has rotation about the <i>y</i> -axis enabled, <i>false</i> otherwise.
<i>bool</i>	<i>D.set_x_rotation(bool b)</i>	enables (disables) rotation about the <i>x</i> -axis.
<i>bool</i>	<i>D.set_y_rotation(bool b)</i>	enables (disables) rotation about the <i>y</i> -axis.
<i>bool</i>	<i>D.get_elim()</i>	returns the hidden line elimination flag.
<i>bool</i>	<i>D.set_elim(bool b)</i>	sets the hidden line elimination flag to <i>b</i> . If <i>b</i> is <i>true</i> , hidden lines will be eliminated, if <i>b</i> is <i>false</i> , hidden lines will be shown.
<i>bool</i>	<i>D.get_solid()</i>	returns the <i>solid</i> flag of <i>D</i> .
<i>bool</i>	<i>D.set_solid(bool b)</i>	sets the <i>solid</i> flag of <i>D</i> to <i>b</i> . If <i>b</i> is <i>true</i> and the current graph of <i>D</i> is a planar map, its faces will be painted in different grey scales, otherwise the faces will be painted white.
<i>bool</i>	<i>D.get_draw_edges()</i>	return <i>true</i> , if edges will be drawn, <i>false</i> otherwise.
<i>bool</i>	<i>D.set_draw_edges(bool b)</i>	enables (disables) the redraw of the edges of <i>D</i> .
<i>string</i>	<i>D.get_message()</i>	returns the message that will be displayed on top of the drawing area of the window.

<i>string</i>	<i>D.set_message(string msg)</i>	sets the message that will be displayed on top of the drawing area of the window to <i>msg</i> .
<i>void</i>	<i>D.set_node_color(color c)</i>	sets the color of all nodes of <i>D</i> to <i>c</i> .
<i>void</i>	<i>D.set_edge_color(color c)</i>	sets the color of all edges of <i>D</i> to <i>c</i> .
<i>color</i>	<i>D.get_color(node v)</i>	returns the color of node <i>v</i> .
<i>color</i>	<i>D.set_color(node v, color c)</i>	sets the color of node <i>v</i> to <i>c</i> .
<i>color</i>	<i>D.get_color(edge e)</i>	returns the color of edge <i>e</i> .
<i>color</i>	<i>D.set_color(edge e, color c)</i>	sets the color of edge <i>e</i> to <i>c</i> .
<i>bool</i>	<i>D.get_arrow(edge e)</i>	returns <i>true</i> , if <i>e</i> will be painted with an arrow, <i>false</i> otherwise.
<i>bool</i>	<i>D.set_arrow(edge e, bool ar)</i>	if <i>ar</i> is <i>true</i> , <i>e</i> will be painted with an arrow, otherwise without an arrow.
<i>void</i>	<i>D.get_d2_position(node_array<point>& d2pos)</i>	returns the two-dimensional positions of the nodes of the graph of <i>D</i> in <i>d2pos</i> .

Chapter 19

Implementations

19.1 User Implementations

User-defined data structures can be used as actual implementation parameters provided they fulfill certain requirements.

19.1.1 Dictionaries

Any class *dic_impl* that provides the following operations can be used as actual implementation parameter for the `_dictionary< K,I,dic_impl>` and the `_d_array< I,E,dic_impl>` data types (cf. sections Dictionaries and Dictionary Arrays).

```
class dic_impl {  
  
    virtual int  cmp(GenPtr, GenPtr) const = 0;  
    virtual int  int_type()           const = 0;  
    virtual void clear_key(GenPtr&)   const = 0;  
    virtual void clear_inf(GenPtr&)   const = 0;  
    virtual void copy_key(GenPtr&)    const = 0;  
    virtual void copy_inf(GenPtr&)    const = 0;  
  
public:  
  
    typedef ... item;  
  
    dic_impl();  
    dic_impl(const dic_impl&);  
    virtual ~dic_impl();  
  
    dic_impl& operator=(const dic_impl&);  
  
    GenPtr key(dic_impl_item) const;
```

```
GenPtr inf(dic_impl_item) const;

dic_impl_item insert(GenPtr,GenPtr);
dic_impl_item lookup(GenPtr) const;
dic_impl_item first_item() const;
dic_impl_item next_item(dic_impl_item) const;

dic_impl_item item(void* p) const
{ return dic_impl_item(p); }

void change_inf(dic_impl_item,GenPtr);
void del_item(dic_impl_item);
void del(GenPtr);
void clear();

int size() const;
};
```

19.1.2 Priority Queues

Any class *prio_impl* that provides the following operations can be used as actual implementation parameter for the *_priority_queue*< *K,I,prio_impl*> data type (cf. section Priority Queues).

```
class prio_impl $\{$

    virtual int  cmp(GenPtr, GenPtr) const = 0;
    virtual int  int_type()             const = 0;
    virtual void clear_key(GenPtr&)     const = 0;
    virtual void clear_inf(GenPtr&)     const = 0;
    virtual void copy_key(GenPtr&)      const = 0;
    virtual void copy_inf(GenPtr&)      const = 0;

public:

typedef ... item;

    prio_impl();
    prio_impl(int);
    prio_impl(int,int);
    prio_impl(const prio_impl&);
    virtual ~prio_impl();

    prio_impl& operator=(const prio_impl&);

    prio_impl_item insert(GenPtr,GenPtr);
    prio_impl_item find_min() \ const;
    prio_impl_item first_item() const;
    prio_impl_item next_item(prio_impl_item) const;

    prio_impl_item item(void* p) const
    { return prio_impl_item(p); }

    GenPtr key(prio_impl_item) const;
    GenPtr inf(prio_impl_item) const;

    void del_min();
    void del_item(prio_impl_item);
    void decrease_key(prio_impl_item,GenPtr);
    void change_inf(prio_impl_item,GenPtr);
    void clear();

    int  size()  const;
};
```

19.1.3 Sorted Sequences

Any class *seq_impl* that provides the following operations can be used as actual implementation parameter for the $_sortseq\langle K, I, seq_impl \rangle$ data type (cf. section Sorted Sequences).

```
class seq_impl {

    virtual int  cmp(GenPtr, GenPtr) const = 0;
    virtual int  int_type()                const = 0;
    virtual void clear_key(GenPtr&)        const = 0;
    virtual void clear_inf(GenPtr&)        const = 0;
    virtual void copy_key(GenPtr&)         const = 0;
    virtual void copy_inf(GenPtr&)         const = 0;

public:

    typedef ... item;

    seq_impl();
    seq_impl(const seq_impl&);
    virtual ~seq_impl();

    seq_impl& operator=(const seq_impl&);
    seq_impl& conc(seq_impl&);

    seq_impl_item insert(GenPtr, GenPtr);
    seq_impl_item insert_at_item(seq_impl_item, GenPtr, GenPtr);
    seq_impl_item lookup(GenPtr) const;
    seq_impl_item locate(GenPtr) const;
    seq_impl_item locate_pred(GenPtr) const;
    seq_impl_item succ(seq_impl_item) const;
    seq_impl_item pred(seq_impl_item) const;
    seq_impl_item item(void* p) const
    { return seq_impl_item(p); }

    GenPtr key(seq_impl_item) const;
    GenPtr inf(seq_impl_item) const;

    void del(GenPtr);
    void del_item(seq_impl_item);
    void change_inf(seq_impl_item, GenPtr);
    void split_at_item(seq_impl_item, seq_impl&, seq_impl&);
    void reverse_items(seq_impl_item, seq_impl_item);
    void clear();

    int  size() const;
};
```

Appendix A

Technical Information

This chapter provides information about installation and usage of LEDA, the interaction with other software packages, and an overview of all currently supported system platforms.

A.1 LEDA Library and Packages

The implementations of most LEDA data types and algorithms are precompiled and contained in one library `libleda` that can be linked with C++ application programs.

LEDA is available either as source code package or as object code package for the platforms listed in Section Platforms. Information on how to obtain LEDA can be found at <http://www.algorithmic-solutions.com/index.php/products/leda-for-c>

Sections Source Contents ff. describe how to compile the LEDA libraries in the source code package for Unix (including Linux and CygWin) and Microsoft Windows. Section http://www.algorithmic-solutions.info/leda_manual/Object_Code_on.html and Section http://www.algorithmic-solutions.info/leda_manual/DLL_s_MS_Visual.html describe the installation and usage of the object code packages for Unix and Windows, respectively.

A.2 Contents of a LEDA Source Code Package

The main directory of the GUI source code package should contain at least the following files and subdirectories:

<code>Readme.txt</code>	Readme File
<code>CHANGES (please read !)</code>	most recent changes
<code>FIXES</code>	bug fixes since last release
<code>license.txt</code>	license text
<code>lconfig</code>	configuration command for unix
<code>lconfig.bat</code>	configuration command for windows
<code>Makefile</code>	make script
<code>confdir/</code>	configuration directory
<code>incl/</code>	include directory
<code>src/</code>	source files compiled into the LEDA Free Edition
<code>src1/</code>	other source files
<code>test/</code>	example and test programs
<code>demo/</code>	demo programs

A.3 Source Code on UNIX Platforms

Source Code Configuration on UNIX

Important remark: When compiling the sources on Unix- or Linuxsystems the development packages for X11 and Xft should be installed. On Ubuntu, for instance, you should call

```
sudo apt-get install libx11-dev
sudo apt-get install libxft-dev
```

1. Go to the LEDA main directory.
2. Type: `lconfig <cc> [static | shared]`

where `<cc>` is the name (or command) of your C++ compiler and the optional second parameter defines the kind of libraries to be generated. Please note that as far as Unix systems go, we currently only support several Linux distributions. LEDA might work on other Unix systems, too - it was originally developed, for instance, on SunOS - but there is no guarantee for that.

Examples: `lconfig CC`, `lconfig g++`, `lconfig sunpro shared`

`lconfig` without arguments prints a list of known compilers.

If your compiler is not in the list you might have to edit the `<LEDA/sys/unix.h>` header file.

LEDA Compilation on UNIX

Type `make` for building the object code library `libleda.a` (`libleda.so` if shared libraries are used). The `make` command will also have another library created named `libGeoW.a`; it only deals with the data type `GeoWin`. There is no shared version of the this library available.

Now follow the instructions given in Section `UnixObjectCodePackage`.

A.4 Source Code on Windows with MS Visual C++

Source Code Configuration for MS Visual C++

1. Setting the Environment Variables for Visual C++:
The compiler `CL.EXE` and the linker `LINK.EXE` require that the environment variables `PATH`, `INCLUDE`, and `LIB` have been set properly.
Therefore, when compiling LEDA, simply open the proper command prompt that

comes with the Visual Studio. The environment variables are then set as required. Just start the x86 (when compiling for a 32 bit platform) or the x64 (when compiling for a 64 bit platform) Native Tools Command Prompt.

2. Go to the LEDA main directory.

3. Type: `lconfig [msc | msc-mt | msc64-mt | msc64-mt-15 | msc-mt-15] [dll] [md | mt | mdd | mtd]`

Remark: When using MS Visual C++ to compile LEDA you have to choose `msc` for 32 bit single-threaded compilation, `msc-mt` for 32 bit multi-threaded compilation, `msc64` for 64 bit single-threaded compilation, and `msc64-mt` for 64 bit multi-threaded compilation. When using MS Visual Studio 2015 or later Visual Studio versions, you should use `msc-mt-15` and `msc64-mt-15` respectively. When building an application with LEDA and MS Visual Studio C++ the LEDA library you use depends on the Microsoft C runtime library you intend to link with. Your application code and LEDA both must be linked to the same Microsoft C runtime library; otherwise serious linker or runtime errors may occur. The Microsoft C runtime libraries are related to the compiler options as follows

C Runtime Library	Option
LIBCMT.LIB	-MT
LIBCMTD.LIB	-MTd
MSVCRT.LIB	-MD
MSVCRTD.LIB	-MDd

In order to get the suitable Libs or DLL please choose the corresponding option in the call of `lconfig`.

LEDA Compilation with MS Visual C++

Type `make_lib` for building the object code libraries

static:	<code>libleda.lib</code>	LEDA library without GeoWin
	<code>libGeoW.lib</code>	GeoWin library
dynamic:	<code>leda.dll, leda.lib</code>	
	<code>libgeow.lib</code>	

Remarks: The current LEDA package supports only the dynamic version; therefore setting `dll` in the `lconfig` call is mandatory at the moment. GeoWin is currently not available as a DLL and will always be build as a static library.

Now follow the instructions given in the corresponding section for the Windows object code package (Section `WinObjectCodePackage` ff.).

A.5 Usage of Header Files

LEDA data types and algorithms can be used in any C++ program as described in this manual (for the general layout of a manual page please see Chapter LEDA Manual Page). The specifications (class declarations) are contained in header files. To use a specific data type its header file has to be included into the program. In general the header file for data type xyz is `<LEDA/group/xyz.h>`. The correct choice for group and xyz is specified on the type's manual page.

A.6 Object Code on UNIX

Files and Directories

To compile and link your programs with LEDA, the LEDA main directory should contain at least the following files and subdirectories:

Readme.txt	Readme File
Install/unix.txt	txt-version of this section
incl/	the LEDA include directory
libleda.a (libleda.so)	the LEDA library

The static library has the extension `.a`. If a shared library is provided it has extension `.so`.

Preparations

Unpacking the LEDA distribution file `LEDA-<ver>-<sys>-<cc>.tar.gz` will create the LEDA root directory "`LEDA-<ver>-<sys>-<cc>`". You might want to rename it or move it to some different place. Let `<LEDA>` denote the final complete path name of the LEDA root directory.

To install and use the Unix object code of LEDA you have to modify your environment as follows:

- Set the environment variable `LEDAROOT` to the LEDA root directory:

```
csh/tcsh: setenv LEDAROOT <LEDA>
```

```
sh/bash: LEDAROOT=<LEDA>
         export LEDAROOT
```

- Shared Library: (for solaris, linux, irix, osf1)
If you planning to use the shared library include `$LEDAROOT` into the `LD_LIBRARY_PATH` search path.
- Make sure that the development packages for X11 and Xft have been installed. On Ubuntu, for instance, you should have called
`sudo apt-get install libx11-dev`
`sudo apt-get install libxft-dev`

Compiling and Linking Application Programs

1. Use the `-I` compiler flag to tell the compiler where to find the LEDA header files.

```
CC (g++) -I$LEDAROOT/incl -c file.cpp
```

2. Use the `-L` compiler flag to tell the compiler where to find the library.

```
CC (g++) -L$LEDAROOT file.o -lleda -lX11 -lXft -lm
```

When using graphics on Solaris systems you might have to link with the system socket library and the network services library as well:

```
CC (g++) ... -lleda -lX11 -lXft -lsocket -lnsl -lm
```

Remark: The libraries must be given in the above order.

3. Compile and link simultaneously with

```
CC (g++) -I$LEDAROOT/incl -L$LEDAROOT file.c -lleda -lX11 -lXft -lm
```

When using the multi-threaded version of LEDA you also have to set the flags `LEDA_MULTI_THREAD` and `pthread` during compilation (`-DLEDA_MULTI_THREAD -pthread`) and you have to additionally link against the `pthread` library (`-pthread`). You may want to ask your system administrator to install the header files and libraries in the system's default directories. Then you no longer have to specify header and library search paths on the compiler command line.

Example programs and demos

The source code of all example and demo programs can be found in `$LEDAROOT/test` and `$LEDAROOT/demo`. Goto `$LEDAROOT/test` or `$LEDAROOT/demo` and type `make` to compile and link all test or demo programs, respectively.

Important Remark: When using `g++` version 4.x.x with optimization level 2 (`-O2`) or higher, you should always compile your sources setting the following flag: `-fno-strict-aliasing`

A.7 Static Libraries for MS Visual C++ .NET

This section describes the installation and usage of static libraries of LEDA with Microsoft Visual C++ .NET.

Remark: The current LEDA package is delivered with dynamic libraries. So this section is only relevant to you if you created static libraries from the source code.

Preparations

To install LEDA you only need to execute the LEDA distribution file `LEDA-<ver>-<package>-win32-<compiler>.exe`. During setup you can choose the name of the LEDA root directory and the parts of LEDA you want to install.

Then you have to set the environment variable `LEDAROOT`. On MS Windows 10 this can be done as follows:

MS Windows 10:

1. Open the Start Search, type in `env`, and choose Edit the system environment variables. A window titled "System Properties" should open.
2. Click the button "Environment variables..." in the lower right corner of the "System Properties" window. A new window opens that allows to add/change/delete the user variables for your account as well as the system variables, provided you have admin rights. If not, change the environment variables of your account.

Add a new user variable `LEDAROOT` with value `<LEDA>`.

In case you are working on a different version of MS Windows, please consult the documentation of your version in order to learn how to perform the corresponding steps. You might have to restart your computer for the changes to take effect.

Files and Directories

To compile and link your programs with LEDA, the LEDA main directory should contain the following files and subdirectories:

<code>Readme.txt</code>	Readme File
<code>incl\</code>	the LEDA include directory

and at least one of the following library sets

- `libleda_md.lib, libgeow_md.lib`
- `libleda_mdd.lib, libgeow_mdd.lib`
- `libleda_mt.lib, libgeow_mt.lib`
- `libleda_mtd.lib, libgeow_mtd.lib`

Compiling and Linking in Microsoft Visual C++ .NET

We now explain how to proceed in order to compile and link an application program using LEDA with MS Visual Studio 2017. If you are using a different version of MS Visual Studio, please read and understand the guidelines below and consult the documentation of your version of the Studio in order to learn how to perform the corresponding steps.

- (1) In the "File" menu of Visual C++ .NET click on "New->Project".
- (2) Choose "Visual C++" as project type and choose "Empty Project".
- (3) Enter a project name, choose a directory for the project, and click "OK".
- (4) After clicking "OK" you have an empty project space. Choose, for instance, "Debug" and "x64" (or "x86" in case you are working on a 32-bit system) in the corresponding pick lists.

If you already have a source file prog.cpp:

- (5) Activate the file browser and add prog.cpp to the main folder of your project
- (6) In the Solution Explorer of your project click on "Source Files" with the right mouse button, then click on "Add-> Add Existing Item" with the left mouse button
- (7) Double click on prog.cpp

If you want to enter a new source file:

- (5') In the Solution Explorer of your project click on "Source Files" with the right mouse button, then click on "Add-> Add New Item" with the left mouse button.
- (6') Choose "C++ File" in Templates, enter a name, and click "Add".
- (7') Enter your code.

- (8) In the Solution Explorer right click on your project and left click on "Properties"
- (9) Click on "C/C++" and "Code Generation" and choose the "Run Time Library" (=compiler flag) you want to use.

If you chose "Debug" in step 4, the default value is now "/MDd", alternatives are "/MD", "/MT", and "/MTd". Notice that you have to use the LEDA libraries that correspond to the chosen flag, e.g., with option "/MDd" you must use libleda_mdd.lib and libgeow_mdd.lib. Using another set of libraries with "/MDd" could lead to serious linker errors.

- (10) Click on "Linker" and "Command Line" and add the name of the LEDA libraries you want to use in "Additional Options" as follows. We use <opt> to indicate the compiler option chosen in Step (9) (e.g., <opt> is mdd for "/MDd").

- libleda_<opt>.lib
for programs using data types of LEDA but not GeoWin.
- libgeow_<opt>.lib libleda_<opt>.lib
for programs using GeoWin

- (11) Click on "VC++ Directories" of the "Properties" window.

- (12) Choose "Include Files" and add the directory `<LEDA>\incl` containing the LEDA include files (Click on the line starting with "Include Files", then click on "Edit..." in the pick list at the right end of that line. Push the "New line" button and then enter `<LEDA>\incl`, or click on the small grey rectangle on the right and choose the correct directory.) Alternatively you can click C/C++→ General in the Configuration Properties and then edit the line "Additional Include Directories".
- (13) Choose "Library Directories" and add the directory `<LEDA>` containing the LEDA libraries.
- (14) Click "OK" to leave the "Properties".
- (15) In the "Build" menu click on "<Build Project>" or "Rebuild <Project>" to compile your program.
- (16) In order to execute your program, click the green play button in the tool bar.

Remark: If your C++ source code files has extension `.c`, you need to add the option `/TP` in "Project Options" (similar to Step (9)), otherwise you will get a number of compiler errors. (Click on "C/C++" and "Command Line". Add `/TP` in "Additional Options" and click "Apply".)

To add LEDA to an existing Project in Microsoft Visual C++ .NET, start the Microsoft Visual Studio with your project and follow Steps (8)–(14) above.

Compiling and Linking Application Programs in a DOS-Box

(a) Setting the Environment Variables for Visual C++:

The compiler `CL.EXE` and the linker `LINK.EXE` require that the environment variables `PATH`, `INCLUDE`, and `LIB` have been set properly. This can easily be ensured by using the command prompts that are installed on your computer with your Visual Studio installation.

To compile programs together with LEDA, the environment variables `PATH`, `LIB`, and `INCLUDE` must additionally contain the corresponding LEDA directories. We now explain how to do that with MS Windows 10. If you are using a different version of MS Windows, please read and understand the guidelines below and consult the documentation of your operating system in order to learn how to perform the corresponding steps.

(b) Setting Environment Variables for LEDA:

MS Windows 10:

1. Open the Start Search, type in `env`, and choose Edit the system environment variables. A window titled "System Properties" should open.

2. Click the button "Environment variables..." in the lower right corner of the "System Properties" window. A new window opens that allows to add/change/delete the user variables for your account as well as the system variables, provided you have admin rights. If not, change the environment variables of your account.

If a user variable PATH, LIB, or INCLUDE already exists, extend the current value as follows:

- extend PATH by <LEDA>
- extend INCLUDE by <LEDA>\incl
- extend LIB by <LEDA>

Otherwise add a new user variable PATH, INCLUDE, or LIB with value <LEDA>, respectively <LEDA>\incl.

You might have to restart your computer for the changes to take effect.

(c) Compiling and Linking Application Programs:

After setting the environment variables, you can use the LEDA libraries as follows to compile and link programs.

Programs that do not use GeoWin:

```
cl <option> prog.cpp libleda.lib
```

Programs using GeoWin:

```
cl <option> prog.cpp libGeoW.lib libleda.lib
```

Possible values for <option> are "-MD", "-MDd", "-MT", and "-MTd". You have to use the LEDA libraries that correspond to the chosen <option>, e.g., with option "-MD" you must use libleda_md.lib. Using another set of libraries with "-MD" could lead to serious linker errors.

Example programs and demos

The source code of all example and demo programs can be found in the directory <LEDA>\test and <LEDA>\demo. Goto <LEDA> and type make_test or make_demo to compile and link all test or demo programs, respectively.

A.8 DLL's for MS Visual C++ .NET

This section describes the installation and usage of LEDA Dynamic Link Libraries (DLL's) with Microsoft Visual C++ .NET.

Preparations

To install LEDA you only need to execute the LEDA distribution file `LEDA-<ver>-<package>-win32-<compiler>.exe`. During setup you can choose the name of the LEDA root directory and the parts of LEDA you want to install.

Then you have to set the environment variable `LEDAROOT`. On MS Windows 10 this can be done as follows:

MS Windows 10:

1. Open the Start Search, type in `env`, and choose Edit the system environment variables. A window titled "System Properties" should open.
2. Click the button "Environment variables..." in the lower right corner of the "System Properties" window. A new window opens that allows to add/change/delete the user variables for your account as well as the system variables, provided you have admin rights. If not, change the environment variables of your account.

Add a new user variable `LEDAROOT` with value `<LEDA>`.

In case you are working on a different version of MS Windows, please consult the documentation of your version in order to learn how to perform the corresponding steps. You might have to restart your computer for the changes to take effect.

Files and Directories

To compile and link your programs with LEDA, the LEDA main directory should contain the following files and subdirectories:

<code>Readme.txt</code>	Readme File
<code>incl\</code>	the LEDA include directory

and at least one of the following dll/library sets

- `leda_md.dll, leda_md.lib, libGeoW_md.lib`
- `leda_mdd.dll, leda_mdd.lib, libGeoW_mdd.lib`
- `leda_mt.dll, leda_mt.lib, libGeoW_mt.lib`
- `leda_mtd.dll, leda_mtd.lib, libGeoW_mtd.lib`

Note: A DLL of GeoWin is currently not available.

Compiling and Linking in Microsoft Visual C++ .NET

We now explain how to proceed in order to compile and link an application program using LEDA with MS Visual Studio 2017. If you are using a different version of MS Visual Studio, please read and understand the guidelines below and consult the documentation of your version of the Studio in order to learn how to perform the corresponding steps.

- (1) In the "File" menu of Visual C++ .NET click on "New->Project".
- (2) Choose "Visual C++" as `project type` and choose "Empty Project".
- (3) Enter a project name, choose a directory for the project, and click "OK".
- (4) After clicking "OK" you have an empty project space. Choose, for instance, "Debug" and "x64" (or "x86" in case you are working on a 32-bit system) in the corresponding pick lists.

If you already have a source file `prog.cpp`:

- (5) Activate the file browser and add `prog.cpp` to the main folder of your project
- (6) In the **Solution Explorer** of your project click on "Source Files" with the right mouse button, then click on "Add-> Add Existing Item" with the left mouse button
- (7) Double click on `prog.cpp`

If you want to enter a new source file:

- (5') In the **Solution Explorer** of your project click on "Source Files" with the right mouse button, then click on "Add-> Add New Item" with the left mouse button.
- (6') Choose "C++ File" in **Templates**, enter a name, and click "Add".
- (7') Enter your code.
- (8) In the **Solution Explorer** right click on your project and left click on "Properties"
- (9a) Click on "C/C++" and "Code Generation" and choose the "Run Time Library" (=compiler flag) you want to use.
 If you chose "Debug" in step 4, the default value is now `/MDd`, alternatives are `/MD`, `/MT`, and `/MTd`. Notice that you have to use the LEDA libraries that correspond to the chosen flag, e.g., with option `/MDd` you must use `libleda_mdd.lib` and `libgeow_mdd.lib`. Using another set of libraries with `/MDd` could lead to serious linker errors.
- (9b) Click on "C/C++" and "Preprocessor" and add `/D "LEDA_DLL"` in "Preprocessor Definitions".

(10) Click on "Linker" and "Command Line" and add the name of the LEDA libraries you want to use in "Additional Options" as follows. We use `<opt>` to indicate the compiler option chosen in Step (9) (e.g., `<opt>` is `mdd` for `/MDd`).

- `leda_<opt>.lib`
for programs that do not use GeoWin
- `libGeoW_<opt>.lib` `leda_<opt>.lib`
for programs using GeoWin

Alternatively, you can include `<LEDA/msc/autolink_dll.h>` in your program and the correct LEDA libraries are linked to your program automatically. If GeoWin is used you need to add `"_LINK_GeoW"` to the "Preprocessor definitions" in Step (9).

(11) Click on "VC++ Directories" of the "Properties" window.

(12) Choose "Include Files" and add the directory `<LEDA>\incl` containing the LEDA include files (Click on the line starting with "Include Files", then click on "Edit..." in the pick list at the right end of that line. Push the "New line" button and then enter `<LEDA>\incl`, or click on the small grey rectangle on the right and choose the correct directory.) Alternatively you can click C/C++-i General in the Configuration Properties and then edit the line "Additional Include Directories".

(13) Choose "Library Directories" and add the directory `<LEDA>` containing the LEDA libraries.

(14) Click "OK" to leave the "Properties"

(15) In the "Build" menu click on "`<Build Project>`" or "`Rebuild <Project>`" to compile your program.

(16) To execute the program "prog.exe" Windows needs to have `leda_<opt>.dll` in its search path for DLL's. Therefore, you need to do one of the following.

- Copy `leda_<opt>.dll` to the `bin\` subdirectory of your compiler or the directory containing "prog.exe".
- Alternatively, you can set the environment variable `PATH` to the directory containing `leda_<opt>.dll` as described below.

(17) In order to execute your program, click the green play button in the tool bar.

Remark: If your C++ source code files has extension `.c`, you need to add the option `/TP` in "Project Options" (similar to Step (9)), otherwise you will get a number of compiler errors. (Click on "C/C++" and "Command Line". Add `/TP` in "Additional Options" and click "Apply".)

If you chose "Debug" for your project type, the default value is `/MDd`, alternatives are `/MD`, `/MT`, and `/MTd`. Notice that you have to use the LEDA libraries that correspond to the chosen flag, e.g., with option `/MDd` you must use `leda_mdd.lib` and `libGeoW_mdd.lib`. Using another set of libraries with `/MDd` could lead to serious linker errors.

To add LEDA to an existing Project in Microsoft Visual C++ .NET, start the Microsoft Visual Studio with your project and follow Steps (8)–(14) above.

Compiling and Linking Application Programs in a DOS-Box

(a) Setting the Environment Variables for Visual C++ .NET:

The compiler CL.EXE and the linker LINK.EXE require that the environment variables PATH, INCLUDE, and LIB have been set properly. This can easily be ensured by using the command prompts that are installed on your computer with your Visual Studio installation.

To compile programs together with LEDA, the environment variables PATH, LIB, and INCLUDE must additionally contain the corresponding LEDA directories. We now explain how to do that with MS Windows 10. If you are using a different version of MS Windows, please read and understand the guidelines below and consult the documentation of your operating system in order to learn how to perform the corresponding steps.

(b) Setting Environment Variables for LEDA:

MS Windows 10:

1. Open the Start Search, type in env, and choose Edit the system environment variables. A window titled "System Properties" should open.
2. Click the button "Environment variables..." in the lower right corner of the "System Properties" window. A new window opens that allows to add/change/delete the user variables for your account as well as the system variables, provided you have admin rights. If not, change the environment variables of your account.
If a user variable PATH, LIB, or INCLUDE already exists, extend the current value as follows:
 - extend PATH by <LEDA>
 - extend INCLUDE by <LEDA>\incl
 - extend LIB by <LEDA>
 Otherwise add a new user variable PATH, INCLUDE, or LIB with value <LEDA>, respectively <LEDA>\incl.

You might have to restart your computer for the changes to take effect.

(c) Compiling and Linking Application Programs:

After setting the environment variables, you can use the LEDA libraries as follows to compile and link programs.

Programs that do not use GeoWin:

```
cl <option> -DLEDA_DLL prog.cpp <libleda.lib>
```

Programs using GeoWin:

```
cl <option> -DLEDA_DLL prog.cpp <libGeoW.lib> <libleda.lib>
```

Possible values for `<option>` are `"-MD"`, `"-MDd"`, `"-MT"`, and `"-MTd"`. You have to use the LEDA libraries that correspond to the chosen `<option>`, e.g., with option `"-MD"` you must use `leda_md.lib` and `libGeoW_md.lib`. Using another set of libraries with `"-MD"` could lead to serious linker errors.

Example programs and demos

The source code of all example and demo programs can be found in the directory `<LEDA>\test` and `<LEDA>\demo`. Goto `<LEDA>` and type `make_test` or `make_demo` to compile and link all test or demo programs, respectively.

A.9 Namespaces and Interaction with other Libraries

If users want to use other software packages like STL together with LEDA in one project avoiding naming conflicts is an issue.

LEDA defines all names (types, functions, constants, ...) in the namespace `leda`. This makes the former macro-based prefixing scheme obsolete. Note, however, that the prefixed names `leda_...` still can be used for backward compatibility. Application programs have to use namespace `leda` globally (by saying `"using namespace leda;"`) or must prefix every LEDA symbol with `"leda::"`.

The second issue of interaction concerns the data type `bool` which is part of the new C++ standard. However not all compilers currently support a `bool` type. LEDA offers `bool` either compiler provided or defined within LEDA if the compiler lacks the support. Some STL packages follow a similar scheme. To solve the existence conflict of two different `bool` type definitions we suggest to use LEDA's `bool` as STL is a pure template library only provided by header files and its defined `bool` type can be easily replaced.

A.10 Platforms

Please visit our web pages for information about the supported platforms.

Appendix B

The golden LEDA rules

The following rules must be adhered to when programming with LEDA in order to write syntactically and semantically correct and efficient LEDA programs. The comprehension of most of the rules is eased by the categorization of the LEDA types given in section rules-exp.

Every rule is illustrated in section rules-exp by one or more code examples.

B.1 The LEDA rules in detail

1. (Definition with initialization by copying) Definition with initialization by copying is possible for every LEDA type. It initializes the defined variable with a copy of the argument of the definition. The next rule states precisely what a copy of a value is.
2. (Copy of a value) Assignment operator and copy constructor of LEDA types create copies of values. This rule defines *recursively* what is meant by the notion “copy of a value”.
 - (a) A copy of a value of a primitive type (built-in type, pointer type, item type) is a bitwise copy of this value.
 - (b) A value x of a simple-structured type is a set or a sequence of values, respectively.
A copy of x is a componentwise copy of all constituent values of this set or this sequence, respectively.
 - (c) A value x of an item-based, structured type is a structured collection of values. A copy of x is a collection of new values, each one of which is the copy of a value of x , the original. The combinatorial structure imposed to the new values is isomorphic to the structure of x , the original.
3. (Equality and identity) This rule defines when two objects x and y are considered as equal and identical, respectively.
 - (a) For objects x and y of a dependent item type, the equality predicate $x==y$ means equality between the values of these objects.

- (b) For objects x and y of an independent item type T , the equality predicate $x==y$ is defined individually for each such item type. In the majority of cases it means equality between the values of x and y , but this is not guaranteed for every type.

Provided that the identity predicate

```
bool identical(const T&, const T&);
```

is defined on type T , it means equality between the values of these objects.

- (c) For objects x and y of a structured type the equality predicate $x==y$ means equality between the values of these objects.
4. (Illegal access via an item) It is illegal to access a container which has been destroyed via an item, or to access a container via the item `nil`.
5. (Initialization of attributes of an independent item type) The attributes of an independent item type are always defined. In particular, a definition with default initialization initializes all attributes. Such a type may specify the initial values, but it need not.

6. (Specification of the structure to be traversed in `forall`-macros)

The argument in a `forall`-macro which specifies the structure to be traversed should not be a function call which returns this structure, but rather an object by itself which represents this structure.

7. (Modification of objects of an item-based container type while iterating over them)

An iteration over an object x of an item-based container type must not add new elements to x . It may delete the element which the iterator item points to, but no other element. The values of the elements may be modified without any restrictions.

8. (Requirements for type parameters)

Every type parameter T must implement the following functions:

a default constructor	<code>T::T()</code>
a copy constructor	<code>T::T(const T&)</code>
an assignment operator	<code>T& T::operator = (const T&)</code>
an input operator	<code>istream& operator >> (istream&, T&)</code>
an output operator	<code>ostream& operator << (ostream&, const T&)</code>

9. (Requirements for linearly ordered types)

In addition to the Requirements for type parameters a linearly ordered type must implement

a compare function	<code>int compare(const T&, const T&)</code>
--------------------	--

Here, for the function `compare()` the following must hold:

- (a) It must be put in the namespace `leda`.
- (b) It must realize a linear order on T .

- (c) If y is the copy of a value x of type T , then `compare(x,y) == 0` must hold.
10. (Requirements for hashed types) In addition to the Requirements for type parameters a hashed type must implement

a hash function	<code>int Hash(const T&)</code>
an equality operator	<code>bool operator == (const T&, const T&)</code>

Here, for the function `Hash()` the following must hold:

- (a) It must be put in the namespace `leda`.
- (b) For all objects x and y of type T : If $x == y$ holds, then so does `Hash(x) == Hash(y)`.

For the equality operator `operator==()` the following must hold:

- (a) It defines an equivalence relation on T .
- (b) If y is a copy of a value x of type T , then $x == y$ must hold.
11. (Requests for numerical types) In addition to the Requirements for type parameters a numerical type must offer the arithmetical operators `operator+()`, `operator-()`, and `operator*()`, as well as the comparison operators `operator<()`, `operator<=()`, `operator>()`, `operator>=()`, `operator==(())`, and `operator!=(())`.

B.2 Code examples for the LEDA rules

```
1. string s("Jumping Jack Flash");
   string t(s); // definition with initialization by copying
   string u = s; // definition with initialization by copying

   stack<int> S;
   // ... fill S with some elements
   stack<int> T(S); // definition with initialization by copying
```

```
2. (a) list_item it1, it2;
      // ...
      it2 = it1; // it2 now references the same container as it1
```

```
(b) array<int> A, B;
    // ...fill A with some elements...
    B = A;
```

Now B contains the same number of integers as A , in the same order, with the same values.

However, A and B do not contain the same objects:

```
int* p = A[0];
int* q = B[0];
p == q; // false
```

A and B are different objects:

```
A == B; // false
```

```
(c) list<int> L, M;
    list_item it1, it2;
    L.push(42);
    L.push(666);
    M = L;
```

L and M now both contain the numbers 666 and 42. These numbers are not the same objects:

```
it1 = L.first();
it2 = M.first();
it1 == it2; // false
```

L and M are different objects as well:

```
L == M; // false
```

In the following assignment the rules c, b, and a are applied recursively (in this order):

```
list< array<int> > L, M;
// ...fill L with some array<int>s
// each of them filled with some elements...
M = L;
```

3. (a)

```
list_item it1, it2;
// ...
it2 = it1; // it2 now references the same container as it1
it1 == it2; // true
```
- (b)

```
point p(2.0, 3.0);
point q(2.0, 3.0);
p == q; // true (as defined for class point)
identical(p, q); // false
point r;
r = p;
identical(p, r); // true
```
- (c)

```
list<int> L, M;
// ...fill L with some elements...
M = L;
L == M; // false
```

```

4. list_item it = L.first();
   L.del_item(it);
   L.contents(it); // illegal access
   it = nil;
   L.contents(it); // illegal access

5. point p(2.0, 3.0); // p has coordinates (2.0, 3.0)
   point q; // q has coordinates but it is not known which

6. edge e;
   forall(e, G.all_edges()) // dangerous!
   { ... }

   // do it like this
   list<edge> E = G.all_edges();
   forall(e, E)
   { ... }

7. list_item it;
   forall(it, L) {
     L.append(1); // illegal; results in infinite loop
     if(L[it] == 5 ) L.del(it); // legal
     if(L[it] == 6 ) L.del(L.succ(it)); // illegal
     L[it]++; // legal
   }

8. class pair {
   public:
     int x, y;

     pair() { x = y = 0; }
     pair(const pair& p) { x = p.x; y = p.y; }
     pair& operator=(const pair& p) {
       if(this != &p) { x = p.x; y = p.y; }
       return *this;
     }
};
